

# POLY VECTORAL REVERSE NAVIGATION

By inventors:

Eric Justin Gould, Janna Buckmaster, Todd Wilkens and Paulus W. Trisnadi

## Background of Invention

5           This invention relates to the selection of a first node which may be a file and references to that first node and the display of the first node and its references. This invention relates to address generation such as found on internet domain name servers. This invention relates to the display and navigation of context lists and relationships between contexts. This invention relates to hypergraph viewing and  
10   navigation.

          Figure 1 illustrates a prior art computer comprising one or more enclosures 10, housing a display device 12, selector device 14, and communication 16 between selector device and system, keyboard 20 and communication 22 between keyboard and system as well as door 24 for removable media. Enclosure 10 is shown herein  
15   with minimal detail by way of illustration. In practice, prior art system enclosures 10 relevant to this invention include but are not limited to television-style cases, desktop computer enclosures, notebook computer enclosures, hand held computer enclosures and rack-mounted computer enclosures. Many of these enclosures 10 incorporate speakers with them, in some instances, being perceived separate from the enclosure  
20   10. Note that there are a number of systems containing more than one enclosure 10, as illustrated, such as a number of desktop computers, televisions with set top boxes and often, additional removable media interfaces such as DVD players. Prior art servers are often rack-mounted and in many circumstances, possess minimal display device 12, selector device 14 and keyboard 20 capabilities. Such minimal display  
25   device 12, selector device 14 and keyboard 20 capabilities may for instance be shared between several servers mounted in one rack.

          Relevant prior art display devices 12 are also widely varied in form and specifics of operation. Relevant prior art display devices 12 may present black and white or color images. Relevant prior art display devices 12 may support either a

vector or raster format. Relevant prior art display devices **12** may present images in either a 2-D, 3-D or multi-dimensional presentation view or collection of views.

Relevant embodiments of selector device **14** include but are not limited to contemporary television channel selectors, home entertainment center remote  
5 controls, computer pointing devices including but not limited to 3-D and 2-D mouse-style pointers, pen tablets, track balls, touch pads, key pads and joysticks. As illustrated in figure **1**, the selector device communicates via physical transport mechanism **16** with an interface housed in enclosure **10**. Relevant physical transport mechanisms **16** include but are not limited to infra-red, micro-wave and other similar  
10 wireless transport layers, as well as wires and optical fiber. The mechanism by which communication is carried out based upon the specific physical transport mechanism employed is not relevant to this invention and will not be discussed for that reason.

Keyboards **20** may be attached to various relevant, prior art systems. Keyboards **20** may house touch pads and mouse sticks which in certain cases are the  
15 relevant selector device **14** of that system.

Figure **2** displays a system block diagram of a prior art computer. The units (**12**, **14**, **20** and **54**) on the left side and bottom of this figure all have a major role in the input and output flows processed and are controlled by the second column of units (**46**, **38**, **42** and **58**), respectively. The data transport mechanisms between units (**12**,  
20 **14**, **20** and **54**) and units (**46**, **38**, **42** and **58**) are represented by arrows (**52**, **16**, **22** and **56**), respectively. These units interact with each other and an overall control circuit labeled digital controller **50** via arrows representing buses (**48**, **44**, **40**, **60**). Additionally, units **30** and **34** interact with digital controller **50** as represented by arrows **32** and **36**, respectively. Digital controller **50** in turn has RAM and  
25 Nonvolatile memory, which it controls and uses to direct the overall operation of relevant prior art systems via buses.

Relevant prior art display devices **12** may present black and white or color images in either a vector or raster format representing images in either a 2-D, 3-D or multi-dimensional presentation view or collection of views. Relevant display data  
30 transport **52** includes but is not limited to NTSC, PAL or various HDTV television protocols of either analog or digital formats, as well as digital and analog RGB and

various flat panel display interface protocols as are often used with computer displays. Many systems today possess a specialized display interface 46, which often incorporates one or more temporary frame buffers and MPEG decoding acceleration technology as well as acceleration technology for a variety of graphics operation. The communication mechanism 48 by which these units interact with the rest of an exemplary prior art system include but are not limited to microcomputer busses such as PCI and AGP as well as dedicated communication paths. Display devices 12 comprise traditional display devices and force feedback tactile and auditory display devices.

10           The selector device 14, selector device communication mechanism 16 and selector interface 38 have been discussed above. The communication between the selector interface 38 and the rest of the system is denoted by arrow 44. Embodiments of arrow 44 include but are not limited to addressable interfaces on computer busses including but not limited to ISA, PCI and USB.

15           Relevant, prior art removable media interface 34 embodiments include but are not limited to optical disk players and electromagnetic disk players of a removable media. These removable media interfaces 34 embodiments further include but are not limited to CD ROM, MPEG and DVD players. Such removable media interface 34 embodiments may further include the ability to write to the storage media as well as play the storage media. Relevant removable media interface 34 embodiments include but are not limited to various SCSI controllers, specialized optical disk controllers, specialized hard disk controllers and RAID disk array controllers. Removable media interface 34 embodiments may further include but are not limited to various continuous play media compression decoders: MPEG decoders and DVD decoders.

20           Relevant prior art communications mechanisms 36 include but are not limited to various SCSI, RAID, ISA and EISA interfaces.

25

Note that in relevant prior art systems, there may be more than one, potentially distinct, removable media interface 34 with potentially distinct interfaces and communication paths 36. One removable media interface 34 might support a writeable CD ROM using a SCSI controller as well as a second DVD-ROM player with its own cabling and player interface 34.

30

Additionally mass storage 30 with communication coupling to digital controller 50 represented by arrow 32 may possess a similar range of operational characteristics: Mass storage 30 embodiments often possess a file management system afforded by operating systems such as UNIX, LINUX, Microsoft Windows™, MacOS™, among others. Mass storage 30 embodiments include but are not limited to various electro-magnetically encoded media as well optically encoded media. Mass storage 30 embodiments include but are not limited to read-only, plus write-once and read often and read-write media. Mass storage 30 embodiments include but are not limited to various SCSI controllers, specialized optical disk controllers, specialized hard disk controllers and RAID disk array controllers. Removable media interface 34 embodiments may further include but are not limited to various continuous play media compression decoders: MPEG decoders and DVD decoders. Relevant prior art communications mechanisms 32 include but are not limited to various SCSI, RAID, ISA and EISA interfaces.

Another relevant source of continuous play media content is provided via external environment 54 communicating with external interface 58 via arrow 56. One relevant external interface 58 is a radio frequency (RF) tuner. Relevant RF tuners 58 include but are not limited to demodulators and/or modulators for various broadcast protocols such as Frequency Modulation (FM), Frequency Division Multiple Access (FDMA), Time Division Multiple Access (TDMA), various spread spectrum protocols, Wavelength Division Multiple Access and wavelet division multiple access. Relevant spread spectrum protocols further include but are not limited to Direct Sequence, Frequency Hopping, Time Hopping and Wideband CDMA. These relevant RF tuners may be connected 56 by wireline or wireless physical transport layers. Relevant wireline physical transports include but are limited to twisted pair, coaxial cable and various optical fiber mechanisms. Relevant wireless physical transports 56 include contemporary broadcast television, High Definition TV (HDTV), as well as various radio frequency, microwave and infra red schemes which may well incorporate an antenna, sensor or array of antennas or sensors.

Another relevant external interface 58 is a modem. Relevant modems include but are not limited to telephone line modems incorporating various transceiver rates which may not be the same for reception as for transmission, as well as various DSL,

ADSL, XDSL, ISDN, Ethernet, Token Ring and ATM interfaces. Physical transport layer 56 for modems include but are not limited to wire line and wireless transport layers. Wire line physical transport layers 56 include but are not limited to telephone lines, twisted pair wire lines, coaxial cabling and various optical fiber technologies.

- 5 Wireless transport layers 56 include but are not limited to directional and non-directional radio, microwave, infrared and optical schemes.

The external environment 54 may be physically located a substantial distance away from the enclosure 10. The external environment 54 is often embodied in many circumstances within a server supporting a network of user systems via  
10 interconnections 56 of these external interfaces 58. Such networks may well support TCP/IP thereby enabling support for the Internet. Such networks may further support one or more Intranets. Such networks may further support one or more Extranets.

Note that in many relevant prior art systems, there is more than one kind of external environment 54 and external interface 58 with potentially different  
15 communication paths 56. A settop box might possess both a RF tuner using an antenna as well as an optical fiber interface to a cable television provider. A notebook computer might well have both a telephone line modem and an Ethernet LAN interface.

Relevant prior art digital controller 50 embodiments include but are not  
20 limited to one or more of the following: general purpose microprocessors, Digital Signal Processors (DSPs), parallel processors, embedded controllers and special purpose system controllers. General purpose microprocessors include but are not limited to various word width Complex Instruction Set Computers (CISC) and Reduced Instruction Set Computers (RISC). DSPs include but are not limited to  
25 various word width computers employing instruction sets allowing at least one add/subtract operation as well as at least one operation comparable to multiplication to be performed in a single instruction cycle. Parallel processors include but are not limited to Single Instruction Multiple Datapath (SIMD), Multiple Instruction Multiple Datapath (MIMD), and hybrid SIMD/MIMD organizations of either uniform or non-  
30 uniform processors. Uniform processor parallel processors employ essentially the same processor uniformly. Non-uniform processor parallel processors do not employ essentially the same processor throughout. Embedded controllers often incorporate

either one or more microprocessors or DSPs along with additional circuitry performing specialized data processing, which may include but is not limited to MPEG stream partitioning and/or decoding, copy protection processing, decryption, authentication and block data error detection and correction. Special purpose system  
5 controllers include but are not limited to various implementations as Programmable Logic Arrays (PLAs), Complex Programmable Logic Devices (CPLDs), Field Programmable Gate Arrays (FPGAs), Application Specific Integrated Circuits (ASICs) and Application Specific Standard Products (ASSPs).

Relevant prior art digital controllers **50** often possess local memory resources  
10 in the form of RAM and nonvolatile memory, interfaced via busses. The RAM may include but is not limited to various forms of RAM and one or more caching banks of RAM. Relevant prior art digital controller **50** embodiments may include but are not limited to one or more of memory caches physically proximate to and possibly contained within the digital controller **50** package or packages. Memory caching may  
15 include but is not limited to separate caching of memory and data. Memory caching may further include but is not limited to multiple layers of cache structures. Distinct processors within the digital controller **50** may further possess distinct caches as well as further localized memory which may in turn include RAM and/or nonvolatile memory. Relevant prior art nonvolatile memory may include but is not limited to  
20 boot ROMs and flash memory circuits which may further emulate disk drives with a form of file management system. Such nonvolatile memory embodiments may be used to initialize the system as well as provide security and accounting information or store content.

Figure 3 displays a prior art file system configuration showing references as  
25 hard aliases of a node **114**. In such configurations, there is an assumption of a root **100** for the file system. Arrows **102**, **104** and **106** indicate directory paths to file folders **108**, **110** and **112**, respectively. File folders **108**, **110** and **112** in turn contain nodes **114**, **126** and **132**, respectively. Node **114** includes **122** file **116** further including content **120**, which is addressed by the file management system as **118**,  
30 specifying a path and filename as "Path1/file1". Note that in many file management systems, **122** is a data structure known variously as a descriptor. Node **126** has a descriptor **128**, which is a soft alias to node **114**. Node **132** has a descriptor **134**,

which is a soft alias to node 114. Access of nodes 126 and/or 132 will be indirect accesses of node 114. When a node is accessed, the access immediately proceeds to the node 114, which accesses the file 116 and the path and filename at 126 or 132 is lost. This mechanism has been used extensively in UNIX-style file management systems. It has been used advantageously to develop extensive software systems such as compilers and VLSI simulation and Computer Aided Design tools and environments.

There is however a persistent problem in such systems: there is no commonly available mechanism by which someone can find all the references to a given node. This can lead to quite inconvenient situations when there is an unknown reference node causing problems in the software environment. By way of example, if there is an incorrect reference to a 3 input nand gate model, rather than a four input nand gate model in a behavioral simulation, it can be quite expensive to track down the faulty reference.

There is another problem inherent in this situation, which is subtle but which has wide-ranging consequences. To discuss the problem requires development of some terms and a look at part of the history of computing. A standard conceptual tool in computer science is the graph, by which is meant a total collection of “points” and a collection of “arcs”, each connecting a first point and a second point. A directed graph is a graph in which the arcs are arrows from a first point to a second point. In an undirected graph, an arc connecting point 1 to point 2 is the same as the same as an arc connecting point 2 to point 1. A path of a graph is an ordered collection of arcs  $1, 2, \dots, A_{n-1}, A_n$  where the first point of 2 is the second point of 1, etc, till the first point of  $A_n$  is the second point of  $A_{n-1}$ . A graph has a cycle if there are two points possessing two distinct paths between those two points, or alternatively, there is a path where the first point of the first arc of the path is the second point of the last arc in the path. An acyclic graph is a graph containing no cycles. A graph is connected if for any two points of the graph, there is a path between those two points. A tree is a connected, acyclic graph. A tree can be seen as having a root point from which all other points in the tree are connected by arcs.

Computer science has found these terms to be extremely useful in providing a basic language about which to conceptualize a number of important mechanisms used

in computing for years. File management systems have been consistently portrayed in operating systems such as UNIX, MSDOS (now Windows) and MacOS (which incorporates a form of UNIX) as hierarchical directory structures. These hierarchical directory structures are acyclic graphs, trees, proceeding from a specific root point (directory). This was and is a major feature of UNIX as well as MSDOS (now Windows) and MacOS. The problem with this hierarchical portrayal of file systems is that hard aliases often fail to conform with the model. Hard aliases essentially create cycles in the graph of a file system. Such a portrayal of a file system as a cyclic graph runs counter to the standard teachings on file management systems as seen in UNIX, MSDOS, Windows and MacOS. The discussion of Figure 3 and the following prior art figures will document situations where users want to see their file structures in the above-mentioned operating systems in ways these operating systems do not even conceptually permit. A standard perspective on file systems (in particular, UNIX file systems) is to be found in “Chapter 2: The File System”, on pages 41-70, The UNIX Programming Environment, by Brian W. Kernighan and Rob Pike, © 1984 Bell Telephone Laboratories, Incorporated, published by Prentice-Hall, Inc.

Figure 4 displays a prior art file system configuration showing references to soft aliases of a node 114. As in figure 1, there is an assumption of a root 100 for the file system. Arrows 102, 104 and 106 indicate directory paths to file folders 108, 110 and 112, respectively. File folders 108, 110 and 112 in turn contain nodes 114, 150 and 170, respectively. Node 114 includes file 116 further including through descriptor 122, content 120, which is addressed by the file management system as 118, specifying a path and filename as “Path1/file1”. Node 150 includes file 152 further including through descriptor 158, content 156, which is addressed by the file management system as 154, specifying a path and filename as “Path2/file2”. Node 170 includes file 172 further including through descriptor 178, content 176, which is addressed by the file management system as 174, specifying a path and filename as “Path3/file3”. Descriptors 158 and 178 act as soft aliases to node 114, essentially mirroring the contents at their respective locations in the file name system. The advantage this brings is the ability to retain the local path and file name at nodes 150 and 170.

The disadvantage is the difficulty discovering whether nodes 150 and 170 are the sources of their file contents, or aliases of it. The persistent problem discussed above also shows up in such system configurations: there is no commonly available mechanism by which someone can find all the soft and hard references to a given  
5 node 114. This can lead to quite inconvenient situations when there is an unknown reference node causing problems in the software environment. By way of example, if there is an incorrect reference to a 3 input nand gate model, rather than a four input nand gate model in a behavioral simulation, it can be quite expensive to track down the faulty reference.

10 Note that in this situation, we again encounter a cyclic graph, when the file management system is “supposed” to be a directory tree. File management systems have been consistently portrayed in operating systems such as UNIX, MSDOS (now Windows) and MacOS (which incorporates a form of UNIX) as hierarchical directory structures. These hierarchical directory structures are connected acyclic graphs, trees,  
15 each proceeding from a specific root point (directory). This was and is a major feature of UNIX as well as MSDOS (now Windows) and MacOS. The problem with this hierarchical portrayal of file systems is that soft aliases often fail to conform with the model. Soft aliases essentially create cycles in the graph of a file system. Such a portrayal of a file system as a cyclic graph runs counter to the standard teachings on  
20 file management systems as seen in UNIX, MSDOS, Windows and MacOS. The users again want to see their file structures in the above-mentioned operating systems in a manner these operating systems do not even conceptually permit.

Figure 5 displays a prior art file system configuration showing references essentially containing the content of a node 114. As in figure 1, there is an assumption  
25 of a root 100 for the file system. Arrows 102, 104 and 106 indicate directory paths to file folders 108, 110 and 112, respectively. File folders 108, 110 and 112 in turn contain nodes 114, 190 and 210, respectively. Node 114 includes through descriptor 122 file 116 further including content 120, which is addressed by the file management system as 118, specifying a path and filename as “Path1/file1”. Node 190 includes file  
30 192 further including through descriptor 198, content 196, which is addressed by the file management system as 194, specifying a path and filename as “Path2/file4”. Node 210 includes file 212 further including through descriptor 218, content 216, which is

addressed by the file management system as **214**, specifying a path and filename as “Path3/file5”.

In the portrayed situation, the content **120** is essentially contained in content **196**, as well as the content **120** is essentially contained in content **216**. In a first  
5 situation, content **120** is essentially copied as content **196**. One example occurs when content **120** is exactly content **196**. A file may have been exactly copied from a remote server to the local system in order to minimize network traffic. Such often happens in communication intensive software tasks, such as behavioral electronic simulations. In another exemplary situation, the content **120** is essentially the same as  
10 content **196**. Consider that file **116** and file **192** may be word-processor versions of the same document, only differing in a type font setting. File **116** and file **192** may be graphics file versions of the same picture, only differing in a color scheme selection, such as differing shades of blue. In yet another exemplary situation, content **120** is essentially incorporated into the content **216**. File **116** may be an earlier version of  
15 file **210**. Alternatively, content **120** may have been used as a background in content **216**. This often occurs in graphical applications: A view **120** has other objects superimposed upon it to create content **216**. Additionally, content **120** may be clipped to a sub-image, which is then incorporated into a large image to create content **216**. Such operations have been seen repeatedly in “clipping out” a face from a photo to  
20 incorporate it into a different background. Note that content **120** may alternatively be an audio sequence and content **210** may be an audio or audio-video sequence. Note that the above examples of image data include but are not limited to both still frame, motion video and integrated motion video and audio. In each of these situations, it is very difficult to create the collection of which nodes essentially reference node **114**  
25 with conventional tools.

Note that essential containment again often creates cyclic graphs traversing a file system. The cyclic graph is encountered, contradicting the file management system, which is “supposed” to be a directory tree. File management systems have been consistently portrayed in operating systems such as UNIX, MSDOS (now  
30 Windows) and MacOS (which incorporates a form of UNIX) as hierarchical directory structures. These hierarchical directory structures are connected acyclic graphs, trees, proceeding from a specific root point (directory). This was and is a major feature of

UNIX as well as MSDOS (now Windows) and MacOS. The problem with this hierarchical portrayal of file systems is that hard aliases often fail to conform with the model. Hard aliases essentially create cycles in the graph of the file system. Such a portrayal of a file system as a cyclic graph runs counter to the standard teachings on file management systems as seen in UNIX, MSDOS, Windows and MacOS. The users want to see their file structures in the above-mentioned operating systems in a manner these operating systems do not even conceptually permit.

Another situation illustrating this involves the use of archive files. Archive files include but are not limited to files containing compressed versions of the content of other files. Often a library with the content of multiple files is to be found in an archive file. Archive file technology is often used to build intermediate versions of software program components prior to the linkage editor phase of program generations, as well as in the form of “dll” (Dynamic Link Libraries) in the Windows systems. Archive file technology is also used to compress information to be transmitted or placed on some form of portable media, such as floppy disk, CD ROM, etc.. In such cases, there is a file which essentially contains the content of one or more other files, again causing arrows from one or more points throughout a file system directory tree to create cycles in the graph. In essence, people repeatedly break the acyclic graph-model of a hierarchical directory structure in the process of using their computers. It is a problem that the standard hierarchical file system model does not account for.

Archival files also reveal another subtle but very significant problem which requires development of some terminology. Hypergraphs are defined as a total collection of points and a collection of hyper-arcs. Each hyper-arc is composed of at least two points. By way of example, assume a first hyper-arc composed of PT1, PT2 and PT3; a second hyper-arc composed of PT2, PT3 and PT1. The first hyper-arc is essentially equal to the second hyper-arc. A directed hypergraph is a hypergraph in which each the points of each hyper-arc are ordered. Assume now that the point ordering of the first and second hyper-arc were as portrayed, then the first hyper-arc would not be essentially equal to the second hyper-arc in this example.

These terms, graphs, trees, acyclic graphs, cycle graphs and hypergraphs have been in use amongst parts of the mathematical and computing community since at

least the 1910's and 1970's. Hypergraphs include graphs. There has been a consistent teaching toward trees, away from graphs in most instances, and very much away from hypergraphs. While hypergraphs are more general than graphs and trees, their discussion outside of limited portions of these communities has not been widespread,  
5 even though they provide the conceptual tools to unify at least the problems discussed above and those outlined in what follows.

A standard approach to graph algorithms in computer science is to be found in Graph Algorithms by Shimon Even, © 1979 Computer Science Press, Inc., ISBN 0-914894-21-8. A less common viewpoint regarding hypergraphs can be found in  
10 Combinatorics: set systems, hypergraphs, families of vectors and combinatorial probability, by Bela Bollobas, © 1986, Cambridge University Press, ISBN 0-521-33703-8. In this work, particularly the preface (pages xi-xii) and the notational introduction (pages 1-3), graphs are defined as specialized hypergraphs, and the tendency to minimize discussion hypergraphs is mentioned.

15 There is a further difficulty revealed in considering Figure 5: consider the situation of copyrighted image material **120** being incorporated into other images. Assume that image material **120** possesses an embedded copyright signature. There are several software tools which embed copyright signatures into content material **120** immune to color changes and which survive the clipping out of relatively small pieces  
20 of the material **120**, such as a face. However, there are no tools available which will construct a context list of nodes essentially referencing this material based upon detecting the copyright signature. Note that many creators of content must now resort to labor intensive mechanisms to search for copyright infringing material. In certain situations, paths **104** and **106** represent virtual paths in a distributed network such as  
25 the Internet. In certain situations, paths **104** and **106** represent paths on a removable media such as a CD ROM or DVD ROM. Note further that the content **120** may be still frame and content **210** may be motion video, or vice versa.

Note that in this situation, we again encounter a cyclic graph, when the file management system is "supposed" to be a directory tree. File management systems  
30 have been consistently portrayed in operating systems such as UNIX, MSDOS (now Windows) and MacOS (which incorporates a form of UNIX) as hierarchical directory structures. These hierarchical directory structures are acyclic graphs, trees, proceeding

from a specific root point (directory). This was and is a major feature of UNIX as well as MSDOS (now Windows) and MacOS. The problem with this hierarchical portrayal of file systems is that soft aliases often fail to conform with the model. Soft aliases essentially create cycles in the graph of a file system. Such a portrayal of a file system as a cyclic graph runs counter to the standard teachings on file management systems as seen in UNIX, MSDOS, Windows and MacOS. The users want to see their file structures in the above-mentioned operating systems in a manner these operating systems do not even conceptually permit.

Figure 6 displays a prior art file system configuration showing references to a revision controlled source **222**. As in figure 1, there is an assumption of a root **100** for the file system. Arrows **102**, **104** and **106** indicate directory paths to file folders **108**, **110** and **112**, respectively. File folders **108**, **110** and **112** in turn contain nodes **230**, **250** and **270**, respectively. Node **230** includes file **232** further including through descriptor **238**, content **236**, which is addressed by the file management system as **234**, specifying a path and filename as "Path1/file b". Node **250** includes file **252** further including through descriptor **258**, content **256**, which is addressed by the file management system as **254**, specifying a path and filename as "Path2/file 7". Node **270** includes file **272** further including through descriptor **278**, content **276**, which is addressed by the file management system as **274**, specifying a path and filename as "Path3/file 8".

In these configurations, there is a separate source of content at node **222**, coupled to the regular file management system as indicated by arrow **224**. Content **236**, **256** and **276** is essentially maintained from node **222**. Changing the contents of node **222** will automatically force the propagation of those changes to nodes **230**, **250** and **270**. The advantage here is that one can update the contents of these representations by modifying just one node. The persistent problem is determining from a node such as **230**, which are the other nodes referencing the same content, and where the source of that content may be found.

Note that in this situation, we again encounter a cyclic graph, when the file management system is "supposed" to be a directory tree. File management systems have been consistently portrayed in operating systems such as UNIX, MSDOS (now Windows) and MacOS (which incorporates a form of UNIX) as hierarchical directory

structures. These hierarchical directory structures are acyclic graphs, trees, proceeding from a specific root point (directory). This was and is a major feature of UNIX as well as MSDOS (now Windows) and MacOS. The problem with this hierarchical portrayal of file systems is that soft aliases often fail to conform with the model. Soft  
5 aliases essentially create cycles in the graph of a file system. Such a portrayal of a file system as a cyclic graph runs counter to the standard teachings on file management systems as seen in UNIX, MSDOS, Windows and MacOS. The users want to see their file structures in the above-mentioned operating systems in a manner these operating systems do not even conceptually permit.

10           Figure 7 displays a prior art domain name lookup table 300. A particular server domain has exactly one entry in such a table, represented as a row. Each row is composed of component entries labeled by way of example as second level 302, first level 304, and URL 306 as shown in row 300. Each server has a unique URL composed of 4 numbers separated by periods. Each of these four numbers ranges  
15 from 0 to 255. Each URL may further have a 16 bit unsigned decimal integer associated with it, called a port address. The URL port numbers have not been shown to simplify the discussion. Each level of the domain name is a collection of characters, usually alpha-numeric which follow a set of additional syntactic rules (which are not the subject of this invention, and will be left silent to simplify the  
20 discussion). A specific domain name, such as “acme.com” could then be represented by a row of entries 310, where “acme” is the second level entry 312, “com” is the first level entry 314, and “1.2.3.141” is the URL entry 316. A second domain name, such as “monkey.com” could then be represented by a row of entries 320, where “monkey” is the second level entry 322, “com” is the first level entry 324, and “101.11.23.121”  
25 is the URL entry 326. A third domain name, such as “uspto.gov” could then be represented by a row of entries 330, where “uspto” is the second level entry 332, “gov” is the first level entry 334, and “121.101.1.5” is the URL entry 336.

          This system has proven itself to be of exemplary utility, supporting an unprecedented increase in communication throughout the world. The four component  
30 URL numbering scheme can support addressing up to 4 billion servers, which is almost as many servers as there are people in the world. With the additional 16 bit port addressing, the use of firewalls, etc. there is enough addressing space to

accommodate service for many years to come. There are however, some uncomfortable issues regarding this scheme. There can be only one “acme.com”, but there are numerous acme companies in the United States. Similarly, suppose several families named “Smith” each want their own web-site. There is no readily available  
5 mechanism by which these name usage collisions can be effectively sorted out. While in general Internet and the World Wide Web have proven themselves to be quite open to experimental changes, this is one area where this is not true.

Figure 8A displays a prior art search engine interface. Such search engines are found in web sites such as the US PTO patent database, on CD ROM product catalogs  
10 and datasheets, as well as many other environments. The details vary widely, but the overall discussion and basic features described herein or variants thereof are found in these applications. There are often two components, a search command component 340 and a search result component 350. The search command component 340 possesses a first command component 342, with an optional operator component 344  
15 and optional command component 346. There are often additional controls to reinitialize the search buffer, start the search, cancel the search, as well as possibly other controls. Once the search has been performed the search result component 350 may contain one or more referencing nodes as illustrated by boxes 352, 354, 356 and 358. Each of these boxes may have some form of salience metric associated with the  
20 match performed in accordance with the search command(s) of the search command component 340.

Salience is a term used hereinafter. In a number of circumstances, such as web-based searches, the term is related to “relevance” metrics. These forms of salience metrics are often based upon frequency of which a word or phrase is found in  
25 a document. Salience metrics can represent a sense of distance between two such words or phrases, or how close such a word or phrase is to the beginning of a web page document.

This relatively simple interface has been a breakthrough for locating information in the ever-increasing complexity of our times. It has helped people,  
30 without ever leaving their home or office, to find and retrieve information from widely diverse sources all over the world in a small fraction of the time it previously took to just get to the local library. Its operation can be frustrating. A search for

common name or surname may return thousands of entries, often with little or no obvious way to reduce the number of results in a coherent fashion.

There is a further problem inherent in existing, user friendly interfaces to databases. Saliency metrics in a database context can refer to measure of satisfaction of some relationship. Consider a financial database, by way of example. A first relationship in the financial database may be the percentage of income paid for state taxes of a given state by a taxable entity. A second relationship may be the percentage of income paid for national taxes by a taxable entity. A third relationship may be the amount of state income tax to be paid by a taxable entity. A fourth relationship may be the amount of national income tax to be paid by a taxable entity. A fifth relationship may be the age and filing status by the taxable entity. A reasonable query of such a database might well include a specific range of percentage state income tax, a specific range of amounts of state income tax and a specific percentage national income tax for a specific combination of age and small business entity.

Such flexible and complex queries are possible with computer programming tools such as Visual Basic, C, C++ and COBOL, to name just a few of the many languages used in such tasks. However, such tools are outside the range of convenience most users of computers can and will tolerate. Further, there is a significant effort necessary to learn such tools and then to debug such programmed interfaces. What is needed is a flexible user interface, which allows the user to perform such queries in a more humanly efficient and painless fashion.

There is an additional, though subtle problem inherent in the standard teachings regarding the portrayal of data in databases. Consider part of the data structure of a patent in the Patent and Trademark Office's patent database. Each patent incorporates a patent number, issue date, filing date, its parentage in terms of being a continuation, divisional, continuation-in-part of a previously filed U.S. patent, which is referenced by its patent number, as well as the inventor list, possibly an assignee, primary examiner and a classification search list. Such an entity is best seen as a hypergraph embedded in a larger hypergraph, such as the database in its entirety or all patents issued on a given day.

Relationships involving multiple attributes, which operations upon many databases often require are not accessible through a graph paradigm. The context of such relationship is often an ordered n-tuple of attributes, where n is often greater than 2. A hyper-arc composed of n ordered attributes is a natural way to portray the entities upon which such relationships act.

The evolution of relationships in computer science and mathematical logic can be seen in considering the definition of relation found on pages 138-139 of The elements of mathematical logic, by Paul Rosenbloom, © 1950 Dover Publications, Inc. The definition is of a subset of a Cartesian cross product of a set with itself. Such a definition was sufficient to handle comparison relationships such as =, > and < as required for integer arithmetic. By the late 1960's and early 1970's, a much more sophisticated definition can be seen on page 11 of Saturated Model Theory, by Gerald E. Sachs, © 1972 W. A. Benjamin, Inc. ISBN 0-805-38380-8. In this definition, a relationship operates on an n-dimensional cross product of potentially different sets. Such a definition is capable of describing the relationships involved in many database activities, although that capability is silent in the text. The interaction between databases and logic matures by the late 1970's, in part due to the development of logic programming languages such as Prolog. This can be seen by examining "Chapter 1: Introduction", pages 1-21, Logic for Problem Solving, by Robert Kowalski, © 1979, Elsevier Science Publishing Co., Inc. 3<sup>rd</sup> printing, 1983 (paperback), ISBN 0-444-00368-1. Note that relationships are acting on elements of these n-dimensional cross products of potentially different sets. Further note the discussion is focused exclusively on graphs and trees. There is no way to visualize these relationships as geometric entities. This limitation persists to this day.

Figure 8B displays a prior art graph based content viewer 360 containing a content viewing component 362 and a graph viewing/navigation component 364. An acyclic graph is displayed in region 364 composed of points 366, 370, 374, 376, 378, 380, 382, 384 and 386, as well as arcs 368, 372, 377, 379, 381, 383, 385, and 390 connecting pairs of these points. Each point is associated with content, which when the point is selected, is displayed in region 362. In certain prior art systems, the portrayal of the graph in region 364 provides more detail to the nearest-graph neighboring points and arcs using an approach known as a "fish-eye" or hyperbolic

view. These content viewers have been seen in embodiments out of Xerox PARC such as the hyperbolic browser and visual thesaurus. In each case, the content viewer is presented with an acyclic graph with each point associated with content, such as displayed in this figure. Further, these prior art viewers require an acyclic graph.

- 5 These viewers teach away from the portrayal of graphs with cycles, much less hypergraphs. This can be seen by examining the document “A Focus+Context Technique Based on Hyperbolic Geometry for Visualizing Large Hierarchies.” By John Lamping, Ramana Rao and Peter Pirolli, © ACM, found on Jan 11, 1999 at the following web-address:
- 10 [http://www.acm.org/sigchi/chi95/proceedings/papers/jl\\_bdy.html](http://www.acm.org/sigchi/chi95/proceedings/papers/jl_bdy.html).

Figure 9 displays a prior art file manager user interface 400. In this example, the interface is composed of a directory tree view 402, a file list viewer 404, and a file snapshot viewer 406. The file list viewer 404, shows the content a currently selected node in the file directory structure as viewed in 402. Directory tree viewers 402

15 typically represent a node as a horizontal component in the display. By way of example, the root of the directory tree being viewed is denoted by the items 410, 412 and 414. Item 410 shows that this node is a directory with file contents through the symbol “+” in the center of the box. Item 414 displays the node name, in this case “ROOT”. Item 416 indicates the extent of containment of the node “ROOT”. Items

20 420, 422, 424 and 426 indicate the node “Speeches”, which is a sub-directory under “ROOT”. Items 430, 432, 434 and 436 indicate a specific file named “Gettysburg.doc”, which is contained in “Speeches”, which is further contained in “ROOT”. Items 440, 442, 444 and 446 indicate a specific file named “I have a dream.doc”, which is contained in “Speeches”, which is further contained in

25 “ROOT”. Note that the filename has been truncated here, in comparison to its representation in 404. Items 450, 452, 454 and 456 indicate an unnamed node, which is a sub-directory under “ROOT”. Items 460, 462, 464 and 456 indicate a specific unnamed file, which is contained in directory 456 which is further contained in “ROOT”. Items 470, 472, 474 and 476 indicate a specific unnamed file, which is

30 contained in 456, which is further contained in “ROOT”. In this example, the node 426 is selected, which contains files “GETTSYBURG.DOC” and “IHAVEADREAM.DOC”. These two files are shown in the file list viewer 404 as 436 and 446. These same files are represented in the directory tree viewer 402 as 436

and 446. The user has further selected “GETTSYBURG.DOC” 436, so that file snapshot viewer 406 shows “Four Score and seven years ago, ...”, which is the start of that speech.

5 This user interface is in widespread application in all of the operating systems mentioned above, in applications such as word processing, spreadsheets, integrated development environments for software, electronics design and image processing. It has however, a consistent frustration for users. Such user interfaces cannot reveal which nodes essentially reference a given node. This regularly leads to a large amount of effort being needed to track down the references by hand. Note again that  
10 the operating system paradigm of a hierarchical directory structure, with its directory tree does not conceptually permit cycle graphs, where the cycles are formed from files essentially referenced by other files.

The frustration has only grown in significance as time has passed. Today there is a major effort underway by providers of creative content such as pictures,  
15 music, motion videos, etc. to uphold copyright protection. This has lead to the development of copyright signature embedding mechanisms for visual data, such as still frames. Determining if a node of content has been essentially incorporated into another content becomes the task of finding the copyright signature. The task of automatically searching a tree of nodes becomes that much more significant.

20 The issue of essential containment, whether through incorporation of an image modified from its node of origin, or a file compressed and incorporated into a larger file, again opens the user to thinking in terms of hypergraphs. And again, the operating systems and the standard user interface paradigm of a hierarchical file directory system expressed consistently as a directory tree teaches away and  
25 discourages such thoughts.

Figure 10 displays a prior art file manager user interface seen as a web page  
480. Such interfaces are found on all of the operating systems mentioned above. They are often composed of a path and filename designating box 482. They also contain a region 484 which displays the contents of the node whose path and filename are  
30 represented in box 482. By way of example, four items are shown contained in this node, 486, 488, 490 and 492. Items 486, 488 and 490 are shown as similarly shaped

icons. Note that in most of these interfaces, there must be some visibly distinguishing characteristic to identify these items as separate nodes. Item 492 is shown as a different icon. Note that icons may further incorporate a text label as shown with item 494, which is associated with item 492. Item 492s is shown as an icon commonly  
5 used to designate a sub-directory of the current node.

This user interface is found in all the above-mentioned operating systems and in many applications. It also has a consistent frustration for users. Such user interfaces cannot reveal which nodes essentially reference a given node. This regularly leads to a large amount of effort being needed to track down the references  
10 by hand.

The frustration similarly has only grown in significance as time has passed. Today there is a major effort underway by providers of creative content such as pictures, music, motion videos, etc. to uphold copyright protection. This has lead to the development of copyright signature embedding mechanisms for visual data, such  
15 as still frames. Determining if a node of content has been essentially incorporated into another content becomes the task of finding the copyright signature. The task of automatically searching a tree of nodes becomes that much more significant.

Note again that the paradigm of a directory tree structure runs counter to what these users are trying to do. These essentially referenced files effectively create  
20 cycles in the file system graph from the user's standpoint. These operating systems (UNIX, MSDOS, Windows and MacOS) teach away from these cyclic graph structures.

Essential references based upon "essentially being contained", open the door to the user thinking in terms of hypergraphs, where the essentially containing files  
25 represent the hyper-arcs and the points of the hypergraph are the files essentially referenced. Note that this is again something these very common operating systems do not conceptually permit.

Figure 11 displays a prior art web browser 500. What is displayed is a fairly typical view of hypertext content found at a web-site address shown in 502. There  
30 has been no portrayal of the numerous other features of these interfaces, such as menu bars, because they are not central to this discussion. For the sake of uniformity of

exposition, various web-sites will be composed of nodes, such as their home page. The node viewer 504 shows a combination of hyperlinks to other nodes 508, 512, and 514. Node viewer 504 also contains text lines 510 and image data 506. Image data 506 may be still frame or change over time. Text data, which is displayed, such as  
5 contained in html files, will be considered image data hereinafter. Image data, which changes over time, will be considered motion video hereinafter.

This user interface is in widespread application in all of the operating systems mentioned above. It also has a consistent frustration for users. Such user interfaces cannot reveal which nodes essentially reference a given node. This regularly leads to  
10 a large amount of effort being needed to track down the references by hand.

The frustration similarly has only grown in significance as time has passed. Today there is a major effort underway by providers of creative content such as pictures, music, motion videos, etc. to uphold copyright protection. This has lead to the development of copyright signature embedding mechanisms for visual data, such  
15 as still frames. Determining if a node of content has been essentially incorporated into another content becomes the task of finding the copyright signature. The task of automatically searching a collection of nodes (perhaps distributed across a directory structure or across a network) becomes that much more significant.

Note again that the paradigm of a directory tree structure runs counter to what  
20 these users are trying to do. These essentially referenced files effectively create cycles in the file system graph from the user's standpoint. These operating systems (UNIX, MSDOS-Windows and MacOS) teach away from these cyclic graph structures.

Essential references based upon "essentially being contained", open the door  
25 to the user thinking in terms of hypergraphs, where the essentially containing files represent the hyper-arcs and the points of the hypergraph are the files essentially referenced. Note that this is again something these very common operating systems do not conceptually permit.

## Summary of invention

This invention includes a method of navigating a collection of nodes by selecting a first node, generating a context list and displaying first node and context list. Each context of the context collection includes a second node essentially  
5 referencing the first node.

This method advantageously provides a mechanism to determine all contexts essentially referencing a first node in a number of useful manners. The reference may be an alias within a file system. The reference may possess identical content.

The reference may further essentially contain the same content. The content  
10 of the second node can be determined to essentially contain the first node content by finding an embedded copyright signature in the second node content which is the same as the copyright signature of the first node content. This is useful in determining which nodes in a file-based system or web-site contain copyright infringing material.

This method also advantageously provides for traversal of referencing  
15 contexts, allowing the selection of a context, making the second node of a selected context, the new first node.

Another aspect of the invention includes a computer program embodied on a computer readable medium for navigating a collection of nodes, comprising code for selecting a first node, code for generating a context list, code for displaying content of  
20 the first node and context list. Each context of the context collection includes a second node essentially referencing the first node.

This computer program advantageously provides code to determine all contexts essentially referencing a first node in a number of useful manners. The reference may be an alias within a file system. The reference may further possess  
25 identical content.

The reference may further essentially contain the same content. Code to determine whether the second node content essentially contains the first node content can look for an embedded copyright signature in the second node content which the

same as the copyright signature of the first node content. This is useful in determining which nodes in a file-based system or web-site contain copyright infringing material.

The computer program also advantageously provides for traversal of referencing contexts, allowing the selection of a context, making the second node of a  
5 selected context, the new first node.

Certain embodiments advantageously provide computer programs for local and distributed processing of the various operations including support of client-server implementations in certain embodiments.

Another aspect of the invention includes a method of generating an address  
10 from a collection of contexts containing steps of receiving a selected attribute collection and generating the address. Each context includes a resolution address and an attribute collection. Each of the attribute collections contains at least one attribute. Whenever the attribute collection of a first context of the context collection is essentially the same as the selected attribute collection, the resolution address of the  
15 first context is selected as the generated address.

For each first and second, different context contained in the context collection, the resolution address of the first context is different from the resolution address of the second context. Further, for each first and second, different context contained in the context collection, the attribute collection of the first context is not essentially the  
20 same as the attribute collection of the second context.

This aspect of the invention advantageously provides for distinct attribute collections for each distinct resolution address. The invention provides a method of selecting at most one resolution address based upon a selected attribute collection being compared to the attribute collection of contexts of the context collection. The  
25 resolution address can be a network address, or more particularly, a TCPIP (Internet) address. The resolution address may further contain a root path. The resolution address may further contain a homepage.

The attribute comparison is that of being essentially the same. In certain embodiments, each context attribute collection contains a first attribute, which is  
30 comprised of two sub-attributes. Two first attributes are essentially the same if they

possess the same sub-attributes, in some order, first to first and second to second, or alternatively, first to second and second to first. This allows for multiple sub-attributes to be compared irrespective of ordering, which is substantially more flexible than standard network addressing schemes of today, which require exact matching of  
5 correspondingly ordered components. This aspect of the invention provides for a significant improvement in the flexibility of organizing address resolution in networks, particularly the Internet.

Another aspect of the invention includes computer programs generating an address from a collection of contexts containing steps of maintaining a context  
10 collection, receiving a selected attribute collection and generating the address. Each context includes a resolution address and an attribute collection comprising at least one attribute. Whenever the attribute collection of the context is essentially the same as the selected attribute collection, the resolution address of that context of the context collection is selected as the generated address.

15 For each first context and second, different context both contained in the context collection, the resolution address of the first context is different from the resolution address of the second context. Further, for each first and second, different context contained in the context collection, the attribute collection of the first context is not essentially the same as the attribute collection of the second context.

20 This aspect of the invention advantageously provides computer programs for distinct attribute collections for each distinct resolution address. The invention provides a method of selecting at most one resolution address based upon a selected attribute collection being compared to the attribute collection of contexts of the context collection. The resolution address can be a network address, or more  
25 particularly, a TCPIP (Internet) address. The resolution address may further contain a root path. The resolution address may further contain a homepage.

The attribute comparison is that of being essentially the same. In certain embodiments, each context attribute collection contains a first attribute, which is comprised of two sub-attributes. Two first attributes are essentially the same if they  
30 possess the same sub-attributes, in some order, first to first and second to second, or alternatively, first to second and second to first. This allows for multiple sub-

attributes to be compared irrespective of ordering, which is substantially more flexible than standard network addressing schemes of today, which require exact matching of correspondingly ordered components. This aspect of the invention provides for a significant improvement in the flexibility of organizing address resolution in  
5 networks, particularly the Internet.

Another aspect of the invention includes a method of navigating a plurality of context lists and a collection of relationships, comprising steps of generating a shared node list and displaying the shared node list. Each context list includes at least one context. Each context includes a node. Each relationship is applied to the contexts of  
10 at least one of the context lists. The generation of the shared node list uses the relationship collection and the plurality of context lists.

This method advantageously provides a much more flexible, friendly interface to search various combinations of relationships and context lists. In certain embodiments, relationships applied to contexts result in either satisfying or not  
15 satisfying the relationship, and the shared node list is generated from contexts where at least one relationship is satisfied. In further embodiments, the shared node list is generated from contexts where all the relationships are satisfied. In certain further embodiments, a satisfaction choice is associated with each relationship and the shared node list is generated from contexts where satisfaction of each relationship applied to  
20 the contexts matches the satisfaction choice of that relationship. This supports complete exploration of contexts satisfying any chosen boolean combination of the relationships.

In other embodiments, relationships applied to contexts advantageously result in a salience belonging to an associated salience range for the relationship. Such  
25 salience ranges are advantageous in examining the results of large database searches and the results of World Wide Web searches. In certain further embodiments, the associated salience range of a relationship includes a numeric range. In further embodiments, that numeric range includes the interval from 0 to 1. In further embodiments, the associated salience range includes integral percentages. In certain  
30 embodiments, there is a satisfaction range associated with the relationship, which is contained in the associated salience range. In certain further embodiments, the generation of shared nodes incorporates nodes where at least one relationship when

applied to the node's context has a salience belonging to the associated satisfaction range of that relationship. In certain further embodiments, the generation of shared nodes incorporates nodes where all relationships when applied to the node's context have a salience belonging to the associated satisfaction range. These embodiments support a much more flexible and detailed examination of search results from one or more relationships.

Another aspect of the invention includes a computer program embodied on a computer readable medium for navigating a plurality of context lists and a collection of relationships. Each context list includes at least one context. Each context includes a node. Each relationship is applied to the contexts of at least one of the context lists. The program comprises code for generating a shared node list and code for displaying the shared node list. The code for generating a shared node list uses the relationship collection and the plurality of context lists.

This aspect of the invention advantageously provides computer programs with a much more flexible, friendly interface to search various combinations of relationships and context lists. In certain embodiments, relationships applied to contexts result in either satisfying or not satisfying the relationship, and the shared node list is generated from contexts where at least one relationship is satisfied. In further embodiments, the shared node list is generated from contexts where all the relationships are satisfied. In certain further embodiments, a satisfaction choice is associated with each relationship and the shared node list is generated from contexts where satisfaction of each relationship applied to the contexts matches the satisfaction choice of that relationship. This supports complete exploration of contexts satisfying any chosen boolean combination of the relationships.

In other embodiment computer programs, relationships applied to contexts advantageously result in a salience belonging to an associated salience range for the relationship. Such salience ranges are advantageous in examining the results of large database searches and the results of World Wide Web searches. In certain further embodiments, the associated salience range of a relationship includes a numeric range. In further embodiments, that numeric range includes the interval from 0 to 1. In further embodiments, the associated salience range includes the integral percentages. In certain of these embodiments, there is a satisfaction range associated

with the relationship, which is contained in the associated salience range. In certain further embodiments, the generation of shared nodes incorporates nodes where at least one relationship when applied to the node's context has a salience belonging to the associated satisfaction range of that relationship. In certain further embodiments, the generation of shared nodes incorporates nodes where all relationships when applied to the node's context have a salience belonging to the associated satisfaction range. These embodiments support a much more flexible and detailed examination of search results from one or more relationships.

Certain embodiments advantageously provide computer programs for local and distributed processing of the various operations including support of client-server implementations in certain embodiments.

Another aspect of the invention includes a method of navigating a hypergraph. The hypergraph includes at least one context list. Each context list contains at least one context. Each context includes a node. The method includes steps of selecting a first context list of the context lists, selecting a first context of the first context list, and displaying the node of the first context of the first context list.

This aspect of the invention provides a method to traverse and display nodes of hypergraphs, a significant generalization of graphs. There are no known methods of displaying hypergraph context nodes. Certain embodiments of the invention provide for directed hypergraphs, with ordered context lists. Certain embodiments support display of the first context. Other embodiments support display of the first context list. Other embodiments support the display of the plurality of context lists.

Another aspect of the invention includes a computer program embodied on a computer readable medium for navigating a hypergraph. The hypergraph includes at least one context list. Each context list contains at least one context. Each context includes a node. The program includes code for selecting a first context list of the context lists, code for selecting a first context of the first context list and code for displaying the node of the first context of the first context list.

This aspect of the invention provides computer programs to traverse and display nodes of hypergraphs, a significant generalization of graphs. There are no known methods of displaying hypergraph context nodes. Certain embodiments of the

invention provide for directed hypergraphs, with ordered context lists. Certain embodiments support display of the first context. Other embodiments support display of the first context list. Other embodiments support the display of the plurality of context lists.

- 5            Certain embodiments advantageously provide computer programs for local and distributed processing of the various operations including support of client-server implementations in certain embodiments.

             These and other advantages of the present invention will become apparent upon reading the following detailed descriptions and studying the various figures of  
10    the drawings.

### **Brief Description of the Drawings**

Figure 1 illustrates a prior art computer;

Figure 2 displays a system block diagram of a prior art computer;

- Figure 3 displays a prior art file system configuration showing references as hard  
15    aliases of a node;

Figure 4 displays a prior art file system configuration showing references as soft aliases of a node;

Figure 5 displays a prior art file system configuration showing references essentially containing the content of a node;

- 20    Figure 6 displays a prior art file system configuration showing references to a revision controlled source database;

Figure 7 displays a prior art domain name lookup table;

Figure 8A displays a prior art search engine interface;

Figure 8B displays a prior art acyclic graph based content viewer;

- 25    Figure 9 displays a prior art file manager user interface;

Figure 10 displays a prior art file manager user interface seen as a web page;

Figure 11 displays a prior art web browser;

Figure 12 portrays two contexts of a first node in accordance with one embodiment;

Figure 13 is a flowchart in accordance with one embodiment;

### **Detailed Description of the Embodiments**

Figures 1 through 11 were discussed previously with reference to the prior related art. Figure 12 portrays two contexts 522 and 550 of a first node 520 in accordance with one embodiment. Arrows 524 and 552 connect from node 520 to the contexts 522 and 550, respectively. Arrow 526 connects from context 522 to node 520. Node 520 is shown as a box containing the letter “C”.

Context 522 is shown as a box further containing boxes labeled 530, 532, 534, 536, 538 and 540. Box 530 is shown containing the letter “C”. Box 532 is shown containing the letter “A”. Box 534 is shown containing the letter “B”. Box 536 is shown containing the letter “K”. Box 538 is shown containing the letter “L”. Box 540 is shown containing the letter “M”.

Context 550 is shown as a box further containing boxes labeled 554, 556, 558, 560 and 562. Box 554 is shown containing the letter “C”. Box 556 is shown containing the letter “F”. Box 558 is shown containing the letter “J”. Box 560 is shown containing the letter “K”. Box 562 is shown containing the letter “Q”.

In accordance with several embodiments of the invention, node 520 is essentially referenced by nodes 530 and 554 in contexts 522 and 550, respectively. Both contexts include nodes other than node 530 and 554. Note that other context may not necessarily have any additional nodes.

In one embodiment of the invention, node 520 is a file with contents “C” with aliases 530 and 554 in context directories 522 and 550, respectively. Both contexts include nodes other than node 530 and 554.

In a second embodiment of the invention, node 520 is a file with contents “C” which have been copied to nodes 530 and 554 in context directories 522 and 550, respectively.

In a third embodiment of the invention, node 520 is a node (file) with contents “C” which have been concatenated into nodes (files) 530 and 554 in contexts (directories) 522 and 550, respectively.

Examples of essentially referencing a node include but are not limited to the use of “#include” statements in the C programming language. In a fourth embodiment of the invention, node 520 is a node (file) is incorporated in this manner into nodes (files) 530 and 554 in contexts (directories) 522 and 550, respectively.

5        Examples of essentially referencing a node include essentially containing the content of a node, as in compression files for text or images. In a fifth embodiment of the invention, node 520 is a node (file) is incorporated in this manner into nodes (files) 530 and 554 in contexts (directories) 522 and 550, respectively.

10        Examples of essentially referencing a node include but are not limited to incorporation of one or more discernible graphical elements from node 520 into the content of nodes 530 and 554. In a sixth embodiment of the invention, node 520 is a node (file) with contents “C” incorporated in this manner into nodes (files) 530 and 554 in contexts (directories) 522 and 550, respectively.

15        A further embodiment of the invention utilizes a copyright signature embedded into the content node 520. Contexts 522 and 550 are determined to essentially contain node 520 when the copyright signature of the content of 520 is detectable in one or more of the nodes of context 522 and 550.

20        Note that in all these embodiments, arrows 524 and 552 go from node 520 to both contexts 522 and 550. In certain embodiments of the invention, these arrows represent at least an initial referencing of the content of node 520 in nodes of context 522 and 550. Such circumstances include but are not limited to the contents of nodes 520 being essentially contained in node 554.

25        In certain embodiments of the invention, arrows 524 and 552 represent the automatic updating of the contents referencing nodes of context 522 and 550. Such circumstances include but are not limited to node 520 referenced by node 530 as a soft alias and node 520 referenced by node 554 as a hard alias. In such circumstances, the arrow 526 from context 522 to node 520 may be interpreted to include but not be limited to modifications of the content of node 530 may cause alterations in the content of node 520.

In certain embodiments, items **522** and **550** may be viewed as hyper-arcs sharing common points, the nodes **C** and **K**, with the collection of **522** and **550** being seen as a hypergraph possessing a total collection of points **A, B, C, F, J, K, L, M** and **Q**. Item **522** may represent the home directory of item **C** as seen by box **530** and arrows **524** and **526**. Item **550** may represent a file essentially containing a copy of node **C** as represented by arrow **552** and box **554**.

In certain alternative embodiments, items **522** and **550** may be viewed as context lists. Context lists **522** and **550** sharing common points, the contexts **C** and **K**. Context lists **522** and **550** may be seen as hyper-arc, with the collection of **522** and **550** being seen as a hypergraph. The hypergraph possesses a total collection of points **A, B, C, F, J, K, L, M** and **Q**., which may be further viewed as contexts, each possessing a node. Item **522** may represent the home directory of item **C** as seen by box **530** and arrows **524** and **526**. Item **550** may represent a file essentially containing a copy of node **C** as represented by arrow **552** and box **554**.

Figure **13** is a flowchart in accordance with one embodiment. Operation **570** initializes the operating environment for performing the following operations. Operation **570** may further allocate systems resources in certain embodiments of the invention.

Operation **572** selects a first node. In certain preferred environments, selection a first node may include but is not limited to selecting a file in a file directory system. In certain preferred environments, selection of a first node may include but is not limited to selecting a component of a compression file, containing as nodes, components which may be expanded to become files. In certain preferred environments, selection a first node may include but is not limited to selecting an image component from an image archive stored in a computer readable media. In certain preferred environments, selection a first node may include but is not limited to selecting an audio sequence from an archive of at least one audio sequence. In certain preferred environments, selection of a first node may include but is not limited to selecting an image component based upon its copyright signature.

Note that in certain embodiments, operation **572** may include but is not limited to receiving the selection from a remote device, such as a client in a client server

system. In certain embodiments, operation 572 may include but is not limited to receiving the selection from a software agent, whose location may either be local or external to the system processing this method. In certain embodiments, operation 572 may include but is not limited to selection being made by a human using a selector  
5 device 14 as discussed above in figures 1 and 2.

Operation 574 generates a context list based upon the first node. Generating a context list involves collecting contexts, each including a second node essentially referencing the first node. Note that there may be more than one node essentially referencing the first node within an individual context. In certain embodiments,  
10 essentially referencing the first node includes but is not limited to aliases of the first node as a file in a file management system. In certain embodiments, essentially referencing the first node includes but is not limited to copies of the content of the node as a file in a file management system. In certain embodiments, essentially  
15 referencing the first node includes but is not limited to an essentially contained version of the first node within the second node. In certain further embodiments, essentially containing a version of the first node within the second node includes but is not limited to incorporating essentially copying the contents of the first node into part or all of the content of the second node. In certain further embodiments,  
20 essentially copying the contents can be determined by detection of an embedded copyright signature of the first node in the second node.

Note that in certain embodiments, operation 574 may include but is not limited to generating a context list for a remote request, either as a client in a client server system or as a server in a client server system. In certain embodiments, operation 574 may include but is not limited to receiving the selection from a software agent, whose  
25 location may either be local or external to the system processing this method. These embodiments will be discussed in greater detail in figure 14 below. In certain embodiments, operation 574 may include but is not limited to generating a context list based upon contexts local to the processing system as discussed above in figures 1 and 2. Such embodiments will also be discussed in greater detail in figure 14 below.  
30 In certain embodiments operation 574 occurs as a single series of actions while in other embodiments, operation 574 occurs spread over time as a functional side effect of other discrete functions.

Operation 578 displays the first node and context list. In certain embodiments, this operation is performed by transmitting the first node and context list to a local unit. In certain other preferred environments, this operation displays the first node and context list on a graphical display device such as 12 as discussed above in figures 1 and 2. These and other embodiments of this operation will be discussed in further detail in figures 16 and 17.

Figure 14 is a detail flowchart for operation 574 of the flowchart 13 in accordance with certain embodiments. Operation 574 starts in many embodiments by initializing various system resources, such as the stack or heap frame of the runtime environment in which it is operating. Operation 580 queries for contexts with a second node essentially referencing the first node. Operation 582 receives response contexts to the query of operation 580. Operation 584 collects response contexts to a context list.

Operation 580 queries for contexts with a second node essentially referencing the first node. Operation 580 in certain embodiments performs the query locally. Operation 580 in certain further embodiments accesses a file management system to search for nodes (files), which are then examined to determine whether they essentially reference the first node. Operation 580 in certain other, further embodiments accesses a file management system to search for nodes contained in contexts (compression archives), which are then examined to determine whether they essentially reference the first node. These contexts are images archives in certain further embodiments. These contexts are motion video sequences in certain further embodiments. These contexts are audio archives in certain further embodiments. These contexts contain multi-media in certain further embodiments.

Operation 580 in certain embodiments performs the query externally. Operation 580 in certain further embodiments accesses a network file management system to search for nodes (files), which are then examined to determine whether they essentially reference the first node. Operation 580 in certain other, further embodiments accesses a network file management system to search for nodes contained in contexts (compression archives), which are then examined to determine whether they essentially reference the first node. These contexts are images archives in certain further embodiments. These contexts are motion video sequences in certain

further embodiments. These contexts are audio archives in certain further embodiments. These contexts contain multi-media in certain further embodiments. Note that these external operations in certain embodiments may involve protocols such as TCP/IP on the Internet. These external operations, in certain further  
5       embodiments, may involve the World Wide Web. These external operations, in certain embodiments, may involve interactions with software agents.

Operation **582** receives response contexts to the query of operation **580**. Operation **580** in certain embodiments has performed the query locally. Receipt of response contexts in certain embodiments entails the reception of messages from  
10       operation **580** as represented by **586**. Messages **586** in certain embodiments may be from a local concurrent process interrogating one or more mass storage units **30**. In other embodiments, these messages **586** may be from a local concurrent process interrogating one or more removable media via removable media interface **34**. In other embodiments, these messages may be from a local concurrent process which  
15       accesses data from an external environment **54** via external interface **58**.

Operation **582** receives response contexts to the query of operation **580**. Operation **580** in certain embodiments performs the query externally. Receipt of response contexts in certain embodiments entails the reception of messages from operation **580** as represented by **586**. Messages **586** in certain embodiments may be  
20       from an external process residing in external environment **54** via external interface **58**. Such an external process may reside on a server in certain embodiments. In certain other embodiments, the external process may reside on a client computer.

Operation **584** collects response contexts to a context list. Receipt of response contexts in certain embodiments entails the reception of messages from operation **582**  
25       as represented by **588**. Note that in certain embodiments, arrow **588** may act as a First In First Out (FIFO) queue. In certain embodiments, operation **582** may perform format conversion operations upon the response contexts which have been received.

Figure **15** is a portrayal of the user perspective on traversal of contexts in accordance with one embodiment. Display region **590** contains four display regions,  
30       labeled **592**, **594**, **596** and **598**. First node **592** is labeled “D” which is diagrammatically shown as essentially references in contexts (regions) **594**, **596** and

**598.** The contexts (regions) **594**, **596** and **598** form the context list of first node **592**. Context **594** is labeled “A”. Context **596** is labeled “B”. Context **598** is labeled “C”.

Display region **600** is labeled “A” with a sub-region **602** labeled “D”. This portrays the user view of selecting context **594** for examination, which is also labeled “A”. The selecting context **594** (A) of the node **592** with context list of **594**, **596** and **598**, with the subsequent modification of the displayed user view to **600** is denoted by arrow **604** which goes from sub-region **594** to region **600**. The return to displaying node **592** and the context list of **594**, **596** and **598**, from the displayed user view of region **600** is denoted by arrow **606** which goes from region **600** to sub-region **594**.

Display region **610** is labeled “B” with a sub-region **612** labeled “D”. This portrays the user view of selecting context **596** for examination, which is also labeled “B”. The selecting context **596** (B) of the node **592** with context list of **594**, **596** and **598**, with the subsequent modification of the displayed user view to **610** is denoted by arrow **614** which goes from sub-region **594** to region **610**. The return to displaying node **592** and the context list of **594**, **596** and **598**, from the displayed user view of region **610** is denoted by arrow **616** which goes from region **610** to sub-region **596**.

Display region **620** is labeled “C” with a sub-region **622** labeled “D”. This portrays the user view of selecting context **598** for examination, which is also labeled “B”. The selecting context **598** (C) of the node **592** with context list of **594**, **596** and **598**, with the subsequent modification of the displayed user view to **620** is denoted by arrow **624** which goes from sub-region **594** to region **620**. The return to displaying node **592** and the context list of **594**, **596** and **598**, from the displayed user view of region **620** is denoted by arrow **626** which goes from region **620** to sub-region **598**.

Figure **16** is a flowchart of operation **578** displaying first node and context list in accordance with an embodiment. Operation **650** displays the first node. Operation **652** displays the context list. In certain embodiments, operation **650** displays the first node locally. In certain other embodiments, operation **650** transmits the first node to an external system. In certain embodiments, operation **652** displays the context list locally. In certain other embodiments, operation **652** transmits the context list to an external system. Note that in certain embodiments operation **650** transmits externally

and operation **652** displays locally. Similarly, in certain embodiments, operation **650** displays locally and operation **652** transmits externally.

Figure **17** is a detail flowchart for displaying a context list **652** of figure **16** in accordance with an embodiment. Operation **654** determines if the display region for the context list should be expanded. In certain embodiments, operation **654** includes selecting a visual cue, such as pressing a mouse button while proximate with an icon or other windows artifact such as a pull-down menu or menu entry, or window button. If the context list display region should be expanded, operation **656** expands the context list display region. These operations are followed by operation **658** displaying the context list in the context list display region. This figure will be discussed in greater detail after a discussion of figures **18A** and **18B**.

Figure **18A** portrays the display **670** of a first node and a context list in accordance with one embodiment. Display region **672** in certain embodiments may display the contents of the first node. Display regions **674**, **676** and **678** display the contexts essentially referencing the first node in certain embodiments. In certain further embodiments, these contexts may be displayed as path and possibly file names pointing to the contexts.

Figure **18B** portrays the display **690** of a first node and a context list in accordance with an embodiment. Display **690** is composed of display regions **692** and **694**. Display region **692** in certain embodiments displays the contents of the first node. Display region **692** in certain other embodiments displays a summary of the contents of the first node. Display region **692** in certain further embodiments displays a thumbnail sketch of the contents of the first node. The first node in certain embodiments contains one or more images. The first node in certain embodiments contains audio sequences, which may be displayed by title, or alternatively by portrayal of the acoustic envelope of the entire sequence or its opening.

Display region **694** is further composed of a short context list **696** and a context list expansion button **698**. The short context list display **696** shows one context as a directory path. In certain embodiments, the short context list display **696** shows more than one context as a directory path. In certain embodiments, the display

region 694 may additionally contain buttons to navigate long context lists which may be too big to be viewed all at once.

Consider now the operations of figure 17 when applied in the following manner to figures 18A and 18B. Assume that Figure 18B is initially displayed. Only a limited part of the context list can be seen. Suppose the user selects to push button 698. The system would perform operation 654 and determine that the user wishes to expand the context list display region. Operation 656 would follow, causing the expansion of the context list display as in figure 18A. Operation 658 would then display the context list in the context list display region as shown in figure 18A.

Note that contraction of the context list display region would use essentially the same approach in reverse.

Figure 19A portrays the relationship between a first node and context list and one user perspective display of the first node and context list in accordance with an embodiment.

The figure is divided into a right and left portion connected by an arrow 708. The left portion is composed of three circular areas labeled A, B and C. Circular region A contains sub-regions 700, 702, 710 and 712. Circular region B contains sub-regions 700, 710, 704 and 714. Circular region C contains sub-regions 700, 712, 714 and 706. The right portion of the figure is composed of a rectangular region 720 surrounded by three wedge shaped regions 722 (labeled A), 724 (labeled B) and 726 (labeled C).

Figure 19B portrays the relationship between a first node and context list and one user perspective display of the first node and context list in accordance with another embodiment.

The figure is divided into a right and left portion connected by an arrow 746. The left portion is composed of three circular areas labeled A, B and C in a similar fashion to figure 19A. Circular region A contains sub-regions 700, 702, 710 and 712. Circular region B contains sub-regions 700, 710, 704 and 714. Circular region C contains sub-regions 700, 712, 714 and 706. The right portion of the figure is composed of a rounded triangular region 730 included in three rounded triangular

regions labeled **A**, **B** and **C**. Rounded triangular region **A** contains sub-regions **730**, **732**, **740** and **742**. Rounded triangular region **B** contains sub-regions **730**, **740**, **734** and **744**. Rounded triangular region **C** contains sub-regions **730**, **742**, **744** and **736**.

Figure 20 portrays the relationship between a first node and context list and one user perspective display of the first node and context list in accordance with another embodiment.

The figure is divided into an upper and lower portion connected by an arrow **768**. The lower portion is composed of three circular areas labeled **A**, **B** and **C** in a similar fashion to figure 19A. Circular region **A** contains sub-regions **700**, **702**, **710** and **712**. Circular region **B** contains sub-regions **700**, **710**, **704** and **714**. Circular region **C** contains sub-regions **700**, **712**, **714** and **706**. Sub-region **700** contains a point designated **750**. The upper portion **760** contains sub-regions **758** and **770**. Sub-region **770** acts as a control panel with sliders **772**, **774** and **776** labeled **A**, **B** and **C**, respectively. Slider **A** has a first slider control point **752**. In certain further embodiments, slider **A** has a second slider control point **762**. Slider **B** has a first slider control point **754**. In certain further embodiments, slider **B** has a second slider control point **764**. Slider **C** has a first slider control point **756**. In certain further embodiments, slider **C** has a second slider control point **766**.

Figure 21 portrays a symmetric parameter domain name viewer in accordance with an embodiment. Viewing region **800** is composed of sub-region **810** and sub-region **812**. Sub-region **810** is shown composed of two field type designators **802** and **806**. Associated with field type designator **802** is a field box **804**, used to designate the specific first URL. Associated with field type designator **806** is a field box **808**, used to designate the specific first URL. Sub-region **812** displays content of a node referenced symmetrically by sub-region **810** URL designators.

By way of example, field type designators have been shown associated with each field box. In certain embodiments, a field type designator may be shown and interpreted as associated with two or more field boxes. In certain embodiments, there may be no separate, associated field type designators displayed.

By way of example, field type designators **802** and **806** are shown as text fields. In certain embodiments, such field type designators may be shown as icons. In certain

By way of example, sub-region **810** is positioned above sub-region **812**. In  
5 other embodiments, sub-region **810** is positioned below sub-region **812**. In other  
embodiments, sub-region **810** is positioned to the right of sub-region **812**. In other  
embodiments, sub-region **810** is positioned to the left of sub-region **812**. In certain  
embodiments, the boundary between sub-region **810** and **812** is clearly marked. In  
certain other embodiments, there is no clearly marked boundary between sub-region  
10 **810** and **812**.

By way of example, sub-region **810** is a single essentially rectangular area of  
the display. In other embodiments, sub-region **810** may be composed of more than  
one rectangular area. In embodiments possessing two or more rectangular areas, these  
rectangular areas may be distributed in any combination of above, below, to the left or  
15 the right of sub-region **812**.

By way of example, sub-region **810** is shown as essentially rectangular. In  
other embodiments, sub-region **810** is shown as essentially being non-rectangular. In  
certain embodiments, sub-region **810** is essentially rounded. In certain further  
embodiments, sub-region **810** is essentially oval. In certain further embodiments,  
20 sub-region **810** is essentially circular.

By way of example, sub-region **812** is shown as essentially rectangular. In  
other embodiments, sub-region **812** is shown as essentially being non-rectangular. In  
certain embodiments, sub-region **812** is essentially rounded. In certain further  
embodiments, sub-region **812** is essentially oval. In certain further embodiments,  
25 sub-region **812** is essentially circular.

By way of example, sub-region **810** adjoins sub-region **812**. In other  
embodiments, sub-region **810** and sub-region **812** are not adjoining. In other  
embodiments, sub-region **812** surrounds sub-region **810**. In still other embodiments,  
sub-region **810** surrounds sub-region **812**.

By way of example, selection of a field type designator **802** permits changing the field type of field box **804**. Selection of field box **804** permits changing the displayed context of field box **804**. The contents of field box **804** are associated with an attribute belonging to an attribute collection. The contents of field box **806** are associated with an attribute belonging to an attribute collection. In certain embodiments, the contents of field box **804** are associated with a first sub-attribute of one attribute. The contents of field box **808** are associated with a second sub-attribute of the same attribute.

The system uses these two sub-attributes to form the attribute. This attribute is then treated as at least part of an attribute collection. The attribute collection is in certain embodiments, submitted to an address generation database engine, which searches the database for an attribute collection essentially the same as the submitted attribute collection. Two attribute collections will be the same if they have the same number of attributes and corresponding attributes are each essentially the same. Instances of attributes composed of sub-attributes as described above are essentially the same if each the sub-attributes of the first instance match some corresponding sub-attribute of the second instance. Note that this correspondence may be direct one-for-one correspondence, or any permutation of the direct correspondence.

Figure **22** portrays a domain name address space **900** as a multi-dimensional structure in accordance with an embodiment. By way of example, the domain name space **900** is shown as a three dimensional space. A first dimension is shown delineated by coordinate values of **902**, **904**, **906** and **908**. A second dimension is shown delineated by coordinate values of **910**, **912**, **914**, **916**, **918** and **920**. A third dimension is shown delineated by coordinate values of **922**, **924**, **926**, **928**, **930** and **932**. Two sub-domains are delineated as **934** and **936**.

In certain embodiments, two of these dimensions may be symmetric, so that the coordinates of the second and third dimension would interchangeably yield the same address. In certain further embodiments, more than two dimensions may be symmetric, so that any permutation of values for those more than two dimensions would interchangeably yield the same address.

In certain alternative embodiments, the dimension axes are associated with specific attribute values and at least one attribute possesses at least two sub-attributes, which may be arranged in any order, and yield the same address. Note that this is from the user's perspective. As will be noted shortly, the crucial issues are the user's perspective and the efficiency of the system.

Figure 23 portrays a symmetric parameter domain name viewer of a trademark space in accordance with an embodiment. Region 1000 is comprised of sub-region 1002 and sub-region 1004. Sub-region 1002 is comprised of a field type designator 1006 associated with a field box 1008. Sub-region 1002 is further comprised of a field type designator 1010 associated with a field box 1012. Sub-region 1002 is further comprised of a field type designator 1014 associated with a field box 1016. Sub-region 1002 is further comprised of a box 1018.

Field type designator 1006 is shown with the text value of "Name". Associated field box 1008 is shown with the text value of "ACME". Field type designator 1010 is shown with the text value of "Industry". Associated with a field box 1012 is shown with the text value of "Steel". Field type designator 1014 is shown with the text value of "Location". Associated with a field box 1016 is shown with the text value of "Detroit, Mich.". Box 1018 is shown with the text value of "Other".

Figure 24A is a flowchart for the generation of an address based upon an attribute collection in accordance with an embodiment. It accesses a database called a context list whose entries are called contexts. Each context is composed of an attribute collection and a resolution address.

There are specific constraints imposed upon this database in certain embodiments. Each context is essentially different from all other context in the context collection in two ways. The attribute collection of each context is not essentially the same as the attribute collection of any other context in the context collection. The resolution address of each context is different from the resolution address of any other context in the context collection. These constraints are advantageous in meeting the requirements for domain name addressing schemes such as employed by the TCP/IP naming protocols such Internet requires.

Operation **1100** starts the process of generating an address based upon an attribute collection. In certain embodiments, the start operation entails system resource allocation. Arrow **1102** designates the flow of execution from starting operation **1100** to operation **1104**. Operation **1104** receives the selected attribute collection. Arrow **1106** designates the flow of execution from operation **1104** to operation **1108**.

Operation **1108** determines whenever an attribute collection of a context is essentially the same as the selected attribute collection. Arrow **1110** designates execution flow from operation **1108** to operation **1112**, whenever an attribute collection of a context is essentially the same as the selected attribute collection. If there is no context whose attribute collection is essentially the same as the selected attribute collection, arrow **1120** designates the flow of execution from operation **1108** to operation **1122**.

Operation **1112** designates selecting the resolution address of the context whose attribute collection is essentially the same as the selected attribute collection as the generated address. Arrow **1114** designates the flow of execution from operation **1112** to operation **1116**. Operation **1116** designates the transmission of the generated address. Arrow **1118** designates the flow of execution from operation **1116** to operation **1126**. Operation **1126** acts as a wait or pause function until a new selected attribute collection is ready to be received in certain embodiments. In certain other embodiments, operation **1126** may determine whether to branch via arrow **1128** or arrow **1132**. Arrow **1128** designates the flow of execution from operation **1126** to operation **1104**, which then repeats the process.

Operation **1122** designates the transmission of a generated address error. Arrow **1124** designates the flow of execution from operation **1122** to **1126**. Arrow **1132** designates the flow of execution from operation **1126** to operation **1134**. Operation **1134** exits from this flowchart, in certain embodiments, releasing systems resources allocated upon starting this flowchart.

In certain embodiments, there is no need to either transmit the generated address or transmit the generated address error. Such embodiments include but are not limited to systems in which the requesting activity for address generation and the

address generation process are essentially local to each other. In such embodiments operations **1116** and **1122** are null operations.

In certain embodiments, arrow **1128** is not found. Operation **1126** may act to exit the process, which is started the next time a selected attribute collection is ready to be received by this process. In such embodiments, operation **1126** may release  
5 systems resources allocated at the start with operation **1100**. In certain embodiments, a message paradigm is employed. Matching one or more templates to a received message may trigger operation **1100**.

Operation **1104** in certain embodiments includes translation of the incoming  
10 selected attribute collection into an internal attribute format. An exemplary embodiment would include the ordering of sub-attributes of an attribute and concatenating these ordered sub-attributes into a string. Such a translation would be applied to each context as it was inserted into the database, so that essential comparisons would be insured completed in one pass without backtracking, as well as  
15 supporting comparison of any permutation of the sub-attributes. In certain embodiments, optimizations supporting rapid indexing, such as hash code generation, supporting rapid indexing into the context list database may be performed by this operation.

Arrow **1106** in certain embodiments acts upon the generated hash code to  
20 trigger operation **1108** acting upon a restricted portion of the context list database. Note that in certain embodiments, the hash code may be no more than a first level attribute, such as “com”, “org” or “gov”. Operation **1108** may be a sequential search of the database or portion of the database in certain embodiments. In other embodiments, operation **1108** may be a concurrent examination of the context  
25 database or portion of the context database.

Figure **24B** is a detail flowchart for operation **1108** of the flowchart of figure **24A** in accordance with an embodiment. Operation **1108** starts in certain embodiments by allocating system resources. Arrow **1140** designates the flow of execution to operation **1142**. Operation **1142** compares the number of attributes in a  
30 context to the number in the selected context attribute collection. If they are not same, arrow **1144** directs execution to operation **1146**, which returns No. If they are

the same, arrow **1148** directs execution to operation **1150**. Operation **1150** selects an attribute of the context attribute collection. Arrow **1152** designates a flow of execution to operation **1154** from operation **1150**. Operation **1154** determines whether the selected attribute is essentially the same as the corresponding attribute of the selected context attribute collection. If it is not essentially the same, arrow **1156** directs execution to operation **1160**, which returns No. Arrow **1162** designates the flow of execution from operation **1154** to operation **1164** which is taken when the selected attribute of the context and the corresponding attribute of the selected attribute collection are essentially the same. Operation **1164** determines if there are more attributes. If there are more attributes, arrow **1166** designates the flow of execution to operation **1150** where an attribute is selected from the remaining attribute of the context attribute collection. Arrow **1168** designates the flow of execution from operation **1164** to operation **1170**, which is taken when there are no more attributes to be compared. Operation **1170** returns Yes.

In certain embodiments, the operations of this flowchart are performed sequentially. In certain other embodiments, various operations may be concurrently executed. Operations **1142** and the cluster of operations **1150**, **1160**, **1164** and **1170** may be concurrently performed. Further embodiments may entail the performance of the comparison operation **1154** upon several attributes at once, with operation **1150** selecting several attributes at once. Operations **1146** and **1160** may be performed by the same instructions in a computer program implementing this process.

In certain embodiments, operations **1146**, **1160** and **1170** may act to release system resources allocated upon starting operation **1108**. In certain further embodiments the instructions of the computer program which releases the system resources may be shared by all or some of these operations.

Figure **25** is a flowchart for the reception and dispatch of messages requesting address generation and context collection maintenance operations in accordance with an embodiment. Operation **1200** starts the process. In certain embodiments, systems resources are allocated for the following operations. Arrow **1222** designates the flow of execution from starting to operation **1202**. Operation **1202** acts to receive messages. Arrow **1204** designates the flow of execution between operation **1202** and **1206**. Operation **1206** determines the message type of received messages. Arrow

1208 designates the flow of execution from operation 1206 to operation 1210. Arrow 1212 designates the flow of execution from operation 1210 to operation 1100. Arrow 1214 designates the flow of execution from operation 1210 to operation 1300.

Operation 1300 processes requests for maintenance operations upon the context  
5 collection and will be described in greater detail in figure 26. Arrow 1220 designates the flow of execution from operation 1210 to operation 1202. Arrow 1224 designates the flow of execution from operation 1210 to operation 1226. Operation 1226 exits the operations of this flowchart.

In certain embodiments, operation 1202 acts to collect more than one message.  
10 Arrow 1222 in such embodiments is activated when either a sufficient number of messages have been received, or additionally in certain further embodiments, when a sufficient period of time has transpired since the reception of the earliest message.

In certain embodiments, operation 1206 occurs concurrently with operation 1202. In certain further embodiments, operations 1202 and 1206 are performed on  
15 separate hardware execution units. In certain further embodiments, the separate hardware execution units processing 1202 and 1206 are local to the same hardware system. In certain further embodiments, the separate hardware execution units processing 1202 and 1206 are local to the same system package. In certain further embodiments, the separate hardware execution units processing 1202 and 1206 are  
20 local to the same integrated circuit.

In certain embodiments, operation 1206 may act upon multiple messages as collected by operation 1202. In certain further embodiments, operation 1206 may further perform operations which in effect group the various messages into those which request address generation and those which request context collection  
25 maintenance operations.

In certain embodiments, operation 1210 occurs concurrently with operation 1206. In certain further embodiments, operations 1206 and 1210 are performed on separate hardware execution units. In certain further embodiments, the separate hardware execution units processing 1206 and 1210 are local to the same hardware  
30 system. In certain further embodiments, the separate hardware execution units processing 1206 and 1210 are local to the same system package. In certain further

embodiments, the separate hardware execution units processing **1206** and **1210** are local to the same integrated circuit.

In certain embodiments, operation **1100** occurs concurrently with operation **1210**. In certain further embodiments, operations **1210** and **1100** are performed on  
5 separate hardware execution units. In certain further embodiments, the separate hardware execution units processing **1210** and **1100** are local to the same hardware system. In certain further embodiments, the separate hardware execution units processing **1210** and **1100** are local to the same system package. In certain further  
10 embodiments, the separate hardware execution units processing **1210** and **1100** are local to the same integrated circuit.

In certain embodiments, operation **1300** occurs concurrently with operation **1202**. In certain further embodiments, operations **1202** and **1300** are performed on separate hardware execution units. In certain further embodiments, the separate hardware execution units processing **1202** and **1300** are local to the same hardware  
15 system. In certain further embodiments, the separate hardware execution units processing **1202** and **1300** are local to the same system package. In certain further embodiments, the separate hardware execution units processing **1202** and **1300** are local to the same integrated circuit.

In certain embodiments, operation **1100** occurs concurrently with operation  
20 **1300**. In certain further embodiments, operations **1300** and **1100** are performed on separate hardware execution units. In certain further embodiments, the separate hardware execution units processing **1300** and **1100** are local to the same hardware system. In certain further embodiments, the separate hardware execution units processing **1300** and **1100** are local to the same system package. In certain further  
25 embodiments, the separate hardware execution units processing **1300** and **1100** are local to the same integrated circuit.

Figure **26** is a detail flowchart for operation **1300** of figure **25** for the processing of context collection maintenance operations in accordance with an embodiment. Arrow **1302** designates the flow of execution from operation **1300** to  
30 operation **1304**. Operation **1304** determines the maintenance request type. Arrow **1306** designates the flow of execution from operation **1304** to operation **1308**.

Operation **1308** receives the context insertion request with proposed attribute collection and proposed resolution address. Arrow **1310** designates the flow of execution from operation **1308** to operation **1312**. Operation **1312** determines whether the proposed context with proposed attribute collection and proposed resolution  
5 address is compatible with the context list database. Arrow **1314** designates the flow of execution from operation **1312** to operation **1316**. Operation **1316** inserts the new context into the context collection. Arrow **1318** designates the flow of execution from operation **1316** to operation **1320**. Operation **1320** determine if there are more maintenance requests to process. Arrow **1322** designates the flow of execution from  
10 operation **1320** to operation **1324**. Operation **1324** exits from the operations of this flowchart. Arrow **1326** designates the flow of execution from operation **1312** to operation **1328**. Operation **1328** transmits a context insertion error. Arrow **1330** designates the flow of execution from operation **1328** to operation **1320**. Arrow **1332** designates the flow of execution from operation **1320** to operation **1304**. Arrow **1334**  
15 designates the flow of execution from operation **1304** to operation **1336**. Operation **1336** processes a context deletion request. Arrow **1338** designates the flow of execution from operation **1336** to operation **1320**.

In certain embodiments, only one context list maintenance request is processed at one time, so that operation **1320** and arrow **1332** are not actively present  
20 in this flowchart.

In certain embodiments, no transmission of context insertion errors may be performed, making operation **1328** inactive in this flowchart, and having the effect of combining arrows **1326** and **1330** into a single arrow.

In certain embodiments, processing only context insertion requests may be  
25 implemented as a standalone process, rendering operations **1304** and **1336** as well as arrows **1334** and **1338** inactive in this flowchart. In certain further embodiments, multiple context insertion requests may be processed, making operation **1304** combined with arrow **1332** lead directly to arrow **1306**.

In certain embodiments, operation **1304** acts upon a collection of maintenance  
30 requests. Thus operations **1308**, **1312**, **1316**, **1328** and **1336** may each act upon more than one request.

Operations **1304**, **1308**, **1312**, **1316**, **1320**, **1328** and **1336** may each be performed concurrently in certain embodiments. In such embodiments the arrows of this flowchart may be implemented as signals and signaling protocols in hardware. In further embodiments, the operations and arrows of this flowchart may be  
5 implemented as concurrent components and their interface signaling within a single system component. In certain further embodiments, the operations and arrows of this flowchart may be implemented as concurrent components and their interface signaling within a single integrated circuit.

Figure **27** is a flowchart for processing the generation of a shared node list and display of the shared node list in accordance with an embodiment. Operation **1400**  
10 starts the operations of the flowchart. Arrow **1402** designates the flow of execution from operation **1400** to operation **1404**. Operation **1404** generates a shared node list from a relationship collection and from a collection of context lists. Arrow **1406** designates the flow of execution from operation **1404** to operation **1408**. Operation  
15 **1408** displays the shared node list. Arrow **1410** designates the flow of execution from operation **1408** to operation **1412**. Operation **1412** exits from the operations of this flowchart.

In certain embodiments, all of these operations are performed on a single computer. In certain further embodiments, these operations are performed  
20 sequentially. In certain embodiments. These operations are performed concurrently.

In certain other embodiments, performance of these operations involves activities on multiple processors. In certain further embodiments, these operations involve the interaction of processors over a network. In certain further embodiments, these operations involve interactions between processors involving a client-server  
25 paradigm. In certain embodiments, these interactions involve the Internet. In certain embodiments, these interactions involve an Intranet. In certain embodiments, these interactions involve an Extranet.

Figure **28** is a detail flowchart for operation **1404** of the flowchart of figure **27** in accordance with an embodiment. Operation **1404** starts by allocating systems  
30 resources in certain embodiments. Arrow **1450** designates the flow of execution from operation **1404** to operation **1452**. Operation **1452** selects a context list from a

plurality of context lists. Arrow **1454** designates the flow of execution from operation **1452** to operation **1456**. Operation **1456** selects a context from the selected context list. Arrow **1458** designates the flow of execution from operation **1456** to operation **1460**. Operation **1460** selects a relationship from the relationship collection. Arrow  
5 **1462** designates the flow of execution from operation **1460** to operation **1464**.

Operation **1464** determines if the selected relationship, when applied to the selected context, is satisfied. Arrow **1466** designates the flow of execution from operation **1464** to operation **1468**, when the selected relationship when applied to the selected context is satisfied. Operation **1468** inserts the node of the selected context  
10 into the shared node list. Arrow **1470** designates the flow of execution from operation **1468** to operation **1484**. Arrow **1472** designates the flow of execution from operation **1464** to operation **1474**, when the selected relationship when applied to the selected context is not satisfied.

Operation **1474** determines whether there are more relationships in the  
15 relationship collection. Arrow **1478** designates the flow of execution from operation **1474** to operation **1480**, when there are no more relationships in the relationship collection. Arrow **1476** designates the flow of execution from operation **1474** to operation **1460**, when there are more relationships in the relationship collection.

Operation **1484** determines whether there are more context lists. Operation  
20 **1480** determines whether there are more contexts in the selected context list. Arrow **1482** designates the flow of execution from operation **1480** to operation **1456**. Arrow **1486** designates the flow of execution from operation **1484** to operation **1488**. Arrow **1490** designates the flow of execution from operation **1488** to operation **1452**. Arrow **1492** designates the flow of execution from operation **1488** to operation **1494**.  
25 Operation **1494** exits the operations of this flowchart.

The overall effect of this flowchart is to describe a process where if one relationship is satisfied by a context, the node of that context is inserted into the shared node list. This activity is performed across all contexts of all context lists. It is shown illustratively as a sequential process acting upon one selected relationship and  
30 one selected context within the selected context list. This is done strictly for

illustrative purposes and is not meant to limit the concurrency of the execution process of the relevant operations.

Operation **1404** further starts by initializing the shared node list in certain embodiments. In certain alternative embodiments, operation **1404** further starts  
5 configuring the shared node list to be extended. Operation **1404** further starts by signaling other potentially concurrent processes which might perform maintenance upon the context list and relationship collection, that they are in use and not available for maintenance activities which might alter the results of this flowchart, in certain embodiments.

10 Operation **1452** selects a context list from a plurality of context lists. After the first iteration of operation **1452** within the execution of this flowchart, the selection chooses context lists not previously selected, in certain embodiments.

Operation **1456** selects a context from the selected context list. After the first iteration of operation **1456** within the execution of this flowchart, the selection  
15 chooses contexts not previously selected, in certain embodiments.

Operation **1460** selects a relationship from the relationship collection. After the first iteration of operation **1460** within the execution of this flowchart, the selection chooses relationships not previously selected, in certain embodiments.

Operation **1494** further signals other potentially concurrent processes which  
20 might perform maintenance upon the context list and relationship collection, that they are no longer in use and are available for maintenance activities which might alter the results of this flowchart, in certain embodiments. Operation **1494** may further release systems resources allocated at the start of operation **1404** in certain embodiments.

This flowchart may be sequentially performed in certain embodiments in  
25 essentially the order represented by this flowchart. In certain alternative embodiments, the application of a relationship may be performed first across all contexts of each context list, before a second relationship is applied across all contexts of each context list.

This flowchart may have concurrent operations performed in certain embodiments, such as the application of a relationship to more than one context in parallel. Operation **1456** would select more than one context from the selected context list. Operation **1464** would apply the selected relationship to the multiplicity of  
5 selected contexts concurrently in certain further embodiments. Alternatively, the selection of contexts may act to load a cache memory, while the application of the selected relationship may be performed concurrently in a sequential manner upon the preloaded contexts.

Figure **29** is a detail flowchart for operation **1404** of the flowchart of figure **27**  
10 in accordance with an alternative embodiment. Operation **1404** starts by allocating systems resources in certain embodiments. Arrow **1502** designates the flow of execution from operation **1404** to operation **1504**. Operation **1504** selects a context list from a plurality of context lists. Arrow **1506** designates the flow of execution from operation **1504** to operation **1508**. Operation **1508** selects a context from the  
15 selected context list. Arrow **1510** designates the flow of execution from operation **1508** to operation **1512**. Operation **1512** selects a relationship from the relationship collection. Arrow **1514** designates the flow of execution from operation **1512** to operation **1516**.

Operation **1516** determines if the selected relationship, when applied to the  
20 selected context is satisfied. Arrow **1518** designates the flow of execution from operation **1516** to operation **1520**, when the selected relationship applied to the selected context is satisfied. Arrow **1532** designates the flow of execution from operation **1516** to operation **1530**, when the selected relationship applied to the selected context is not satisfied.

25 Operation **1520** determines if there are more unselected relationships for the selected context of the selected context list. Arrow **1522** designates the flow of execution from operation **1520** to operation **1512**, when there are more unselected relationships. Arrow **1524** designates the flow of execution from operation **1520** to operation **1526**, when there are no more unselected relationships.

30 Operation **1526** inserts the node of the selected context into the shared node list. Arrow **1528** designates the flow of execution from operation **1526** to operation

1530. Operation 1530 determines whether there are more unselected context lists. Operation 1530 determines whether there are more unselected relationships in the relationship collection. Arrow 1534 designates the flow of execution from operation 1530 to operation 1508, when there are more unselected relationships. Arrow 1536  
5 designates the flow of execution from operation 1530 to operation 1538, when there are no more unselected relationships.

Operation 1538 determines whether there are more unselected contexts in the selected context list. Arrow 1540 designates the flow of execution from operation 1538 to operation 1504, when there are more unselected contexts in the selected  
10 context list. Arrow 1542 designates the flow of execution from operation 1538 to operation 1544 when there are no more unselected contexts in the selected context list. Operation 1544 exits the operations of this flowchart.

The overall effect of this flowchart is to describe a process where if all relationships are satisfied by a context, the node of that context is inserted into the  
15 shared node list.

Operation 1404 further starts by initializing the shared node list in certain embodiments. In certain alternative embodiments, operation 1404 further starts configuring the shared node list to be extended. Operation 1404 further starts by signaling other potentially concurrent processes which might perform maintenance  
20 upon the context list and relationship collection, that they are in use and not available for maintenance activities which might alter the results of this flowchart, in certain embodiments.

Operation 1504 selects a context list from a plurality of context lists. After the first iteration of operation 1504 within the execution of this flowchart, the selection  
25 chooses context lists not previously selected, in certain embodiments.

Operation 1508 selects a context from the selected context list. After the first iteration of operation 1508 within the execution of this flowchart, the selection chooses contexts not previously selected, in certain embodiments.

Operation **1512** selects a relationship from the relationship collection. After the first iteration of operation **1512** within the execution of this flowchart, the selection chooses relationships not previously selected, in certain embodiments.

Operation **1544** further signals other potentially concurrent processes which might perform maintenance upon the context list and relationship collection, that they are no longer in use and are available for maintenance activities which might alter the results of this flowchart, in certain embodiments. Operation **1544** may further release systems resources allocated at the start of operation **1404** in certain embodiments.

This flowchart may be sequentially performed in certain embodiments in essentially the order represented by this flowchart. In certain alternative embodiments, the application of a relationship may be performed first across all contexts of each context list, before a second relationship is applied across all contexts of each context list.

This flowchart may have concurrent operations performed in certain embodiments, such as the application of a relationship to more than one context in parallel. Operation **1508** would select more than one context from the selected context list. Operation **1516** would apply the selected relationship to the multiplicity of selected contexts concurrently in certain further embodiments. Alternatively, the selection of contexts may act to load a cache memory, while the application of the selected relationship may be performed concurrently in a sequential manner upon the preloaded contexts.

Figure **30** is a flowchart for processing the generation of a shared node list and display of the shared node list in accordance with an embodiment. Operation **1600** starts the operations of this flowchart. Arrow **1602** designates the flow of execution from operation **1600** to operation **1604**. Operation **1604** associates a satisfaction choice with each relationship. Arrow **1606** designates the flow of execution from operation **1604** to operation **1608**. Operation **1608** generates a shared node list from the relationship collection and collection of context lists. Arrow **1610** designates the flow of execution from operation **1608** to operation **1612**. Operation **1612** displays the shared node list. Arrow **1614** designates the flow of execution from operation **1612** to operation **1616**. Operation **1616** exits the operations of this flowchart.

Operation 1600 starts the operations of this flowchart. In certain embodiments, operation 1600 initializes the shared node list. In certain alternative embodiments, operation 1600 configures the shared node list to accept additional nodes. In certain embodiments, operation 1600 signals other processes performing tasks which may include but are not limited to maintenance operations upon the context lists and relationship collection, that these entities are in use, stalling such operations from being performed. In certain embodiments, this operation allocates temporarily system resources used by the operations of this flowchart.

Operation 1604 associates a satisfaction choice with each relationship. In certain embodiments, operation 1604 associates a default choice as the satisfaction choice with each relationship. In certain embodiments, operation 1604 interacts with other elements of the system to associate the satisfaction choice. In certain further embodiments, operation 1604 interacts with a user to determine the satisfaction choice with at least one relationship. In certain other further embodiments, operation 1604 interacts with a software agent to determine the satisfaction choice with at least one relationship.

Operation 1608 generates a shared node list from the relationship collection and collection of context lists. Operation 1608 will be discussed in greater detail in the flowcharts of figures 31, 32 and 33.

Operation 1408 displays the shared node list. A detailed discussion of this operation can be found above regarding figure 27 and in what follows in the discussion of figures 36A, 36B and 37.

Operation 1616 exits the operations of this flowchart. In certain embodiments, operation 1616 releases temporarily allocated system resources used by the operations of this flowchart. In certain embodiments, operation 1616 signals other processes performing tasks which may include but are not limited to maintenance operations upon the context lists and relationship collection, that these entities are no longer in use, allowing such operations to be performed.

Figure 31 is a detail flowchart for operation 1608 of the flowchart of figure 30 in accordance with an embodiment. Operation 1608 starts the operations of this flowchart, in certain embodiments. Arrow 1700 designates the flow of execution from

operation 1608 to operation 1702. Operation 1702 selects a context list. The execution of operation 1702 selects from previously unselected context lists. Arrow 1704 designates the flow of execution from operation 1702 to operation 1706. Operation 1706 selects a context from the selected context list. Execution of operation 1706 is from previously unselected contexts of the selected context list. Arrow 1708 designates the flow of execution from operation 1706 to operation 1710. Operation 1710 selects a relationship from the relationship collection. Execution of operation 1710 is from previously unselected relationships regarding the selected context of the selected context list. Arrow 1712 designates the flow of execution from operation 1710 to operation 1714.

Operation 1714 determines if the selected relationship applied to the selected context matches the satisfaction choice associated with the selected relationship. Arrow 1716 designates the flow of execution from operation 1714 to operation 1718, when the selected relationship, applied to the selected context, matches the satisfaction choice. Arrow 1730 designates the flow of execution from operation 1714 to operation 1726, when the selected relationship, applied to the selected context, does not match the satisfaction choice.

Operation 1718 determines if there are more relationships in the relationship collection. Arrow 1720 designates the flow of execution from operation 1718 to operation 1722, when there no are more relationships may be selected regarding the selected context of the selected context list. Arrow 1742 designates the flow of execution from operation 1718 to operation 1710, when there are more relationships may be selected regarding the selected context of the selected context list.

Operation 1722 inserts the node of the selected context into the shared node list. Arrow 1724 designates the flow of execution from operation 1722 to operation 1726. Operation 1726 determines whether there are more contexts to select in the selected context list. Arrow 1728 designates the flow of execution from operation 1726 to operation 1706, which is taken when there are more contexts to select in the selected context list. Arrow 1732 designates the flow of execution from operation 1726 to operation 1734, which is taken when there are no more contexts to select in the selected context list.

Operation **1734** determines if more context lists may be selected. Arrow **1736** designates the flow of execution from operation **1734** to operation **1702**, if more context lists may be selected. Arrow **1738** designates the flow of execution from operation **1734** to operation **1740**, if no more context lists may be selected. Operation  
5 **1740** exits the operations of this flowchart.

Operation **1608** starts by allocating systems resources used by operations of this flowchart, in certain embodiments. In certain embodiments, operation **1608** initializes the shared node list. In certain alternative embodiments, operation **1608** configures the shared node list to accept additional nodes. In certain embodiments,  
10 operation **1608** signals other processes performing tasks which may include but are not limited to maintenance operations upon the context lists and relationship collection, that these entities are in use, stalling such operations from being performed. In certain embodiments, this operation allocates temporarily system resources used by the operations of this flowchart.

15 Operation **1740** exits the operations of this flowchart. In certain embodiments, operation **1740** releases temporarily allocated system resources used by the operations of this flowchart. In certain embodiments, operation **1740** signals other processes performing tasks which may include but are not limited to maintenance operations upon the context lists and relationship collection, that these entities are no longer in  
20 use, allowing such operations from being performed.

This flowchart essentially portrays inserting a node of a context from a context list into the shared node list when the satisfaction of each relationship when applied to the context matches the associated satisfaction choice. In certain embodiments, the operations of this flowchart are sequentially performed in essentially the order  
25 represented by this flowchart.

In certain embodiments, certain operations of this flowchart are concurrently performed. In certain embodiments, operation **1706** may act to select more than one context from the selected context list. In certain further embodiments, operation **1706** may act to cache these selected contexts for use by operations **1710**, **1714** and **1722**.

30 In certain embodiments, operations **1710**, **1714** and **1718** may be performed with regards to multiple relationships concurrently. In such embodiments, if

operation **1714** finds any relationship, when applied to a selected context does not match the satisfaction choice of that relationship, the node of the selected context will not be inserted into the shared node list.

In certain embodiments, the relationships may be applied to specific orderings  
5 of a context list. Operation **1706** may act to select more than one context from the selected context list.

Operation **1722** inserts the node of the selected context into the shared node list. In certain embodiments, operation **1722** may insert redundant copies of a node into the shared node list. In certain other embodiments, operation **1722** inserts no  
10 more than one instance of a node into the shared node list.

Figure **32** is a detail flowchart for operation **1714** of figure **31** in accordance with an embodiment. Arrow **1800** designates the flow of execution from operation **1714** to operation **1802**. Operation **1802** determines if the selected relationship applied to the selected context is satisfied. Arrow **1804** designates the flow of  
15 execution from operation **1802** to operation **1806**, when the selected relationship applied to the selected context is satisfied. Arrow **1816** designates the flow of execution from operation **1802** to operation **1818**, when the selected relationship applied to the selected context is not satisfied.

Operation **1806** determines if the satisfaction choice of the selected  
20 relationship is satisfied. Arrow **1808** designates the flow of execution from operation **1806** to operation **1810**, when the satisfaction choice of the selected relationship is satisfied. Arrow **1812** designates the flow of execution from operation **1806** to operation **1814**, when the satisfaction choice of the selected relationship is not satisfied.

25 Operation **1818** determines if the satisfaction choice of the selected relationship is not satisfied. Arrow **1820** designates the flow of execution from operation **1818** to operation **1822**, when the satisfaction choice of the selected relationship is not satisfied. Arrow **1824** designates the flow of execution from operation **1818** to operation **1826**, when the satisfaction choice of the selected  
30 relationship is satisfied.

In certain embodiments, satisfaction is represented as a boolean value, often denoted as a member of the collection of 0 and 1. An alternative representation is as a member of the collection of false and true. As a boolean representation, it may be encoded as a bit of a digitally represented number, which may facilitate performance of parallel or concurrent operations upon more than one relationship in single computer instruction, in certain embodiments. Note that this approach can be seen as comparison of two numbers, one containing bits corresponding to the results of applying relationships to the same context, and the other number whose corresponding bits are the associated satisfaction choices. The operations of this flowchart return Yes if the two numbers exactly identical and No otherwise.

In certain other embodiments boolean representations of multiple context satisfactions may be represented in a single digitally represented number, which may facilitate performance of parallel or concurrent operations in multiple contexts by the same relationship.

Figure 33 is a flowchart for processing the generation of a shared node list and display of the shared node list with in accordance with an embodiment. Operation 1850 starts the operations of this flowchart. Arrow 1852 designates the flow of execution from operation 1850 to operation 1854. Operation 1854 associates a salience range with each relationship. Arrow 1856 designates the flow of execution from operation 1854 to operation 1858. Operation 1858 associates a satisfaction range with each relationship. Arrow 1862 designates the flow of execution from operation 1858 to operation 1860. Operation 1862 generates a shared node list from the relationship collection, satisfaction ranges and collection of context lists. Arrow 1864 designates the flow of execution from operation 1862 to operation 1408. Operation 1408 displays the shared node list. Arrow 1866 designates the flow of execution from operation 1408 to operation 1868. Operation 1868 exits the operations of this flowchart.

Operation 1850 starts the operations of this flowchart. In certain embodiments, operation 1850 initializes the shared node list. In certain alternative embodiments, operation 1850 configures the shared node list to accept additional nodes. In certain embodiments, operation 1850 signals other processes performing tasks which may include but are not limited to maintenance operations upon the

context lists and relationship collection, that these entities are in use, stalling such operations from being performed. In certain embodiments, this operation allocates temporarily system resources used by the operations of this flowchart. In certain further embodiments, the relationship collection is modified to incorporate an  
5 associated salience range.

Operation **1854** associates a salience range with each relationship. In some embodiments, a salience range of a relationship includes a collection of numbers. In some further embodiments, the salience range of a relationship includes a numeric range. In some further embodiments, the salience range of a relationship includes the  
10 numbers 0 and 1. In some further embodiments, the salience range of a relationship includes a numeric range including 0 and 1. In some further embodiments, the salience range of a relationship includes a numeric range of percentages. Operation **1854** may associate differing salience ranges to different relationships within the same relationship collection. By way of example, one salience range may be the count of  
15 the number of times a character string has been found in a document file. In certain embodiments, operation **1854** acts to associate a salience range with newly included relationships of the relationship collection.

Operation **1858** associates a satisfaction range with each relationship. In certain embodiments, the satisfaction range does not overlap the salience range  
20 associated with a relationship. In certain alternative embodiments, the satisfaction range overlaps the salience range associated with a relationship. In certain further embodiments, the satisfaction range is contained in the salience range associated with a relationship. In certain further embodiments, the satisfaction range is the salience range associated with a relationship. In certain embodiments, the satisfaction range is  
25 set to the salience range by default, and modified when requested to a different range.

Operation **1860** generates a shared node list from the relationship collection, satisfaction ranges and collection of context lists. Operation **1860** will be discussed in greater detail in the discussions regarding the flowcharts of figures **34** and **35**.

Operation **1408** displays the shared node list. A detailed discussion of this  
30 operation can be found above regarding figure **27** and in what follows in the discussion of figures **36A**, **36B** and **37**.

Operation **1868** exits the operations of this flowchart. In certain embodiments, operation **1868** releases temporarily allocated system resources used by the operations of this flowchart. In certain embodiments, operation **1868** signals other processes performing tasks which may include but are not limited to maintenance operations upon the context lists and relationship collection, that these entities are no longer in use, allowing such operations to be performed. In certain embodiments, operation **1868** modifies the relationship collection to remove an associated salience range.

In certain embodiments, the operations of this flowchart are sequentially performed. In certain embodiments, the operations of this flowchart are all performed locally to one system. In certain embodiments, the operations of this flowchart are performed across a network incorporating more than one system. In certain further embodiments, operations **1854**, **1858** and **1408** involve interactions on one local system and operation **1860** involves actions on an external system. In certain further embodiments, operations **1854**, **1858** and **1408** involve interactions with one or more users. In certain other, further embodiments, operations **1854**, **1858** and **1408** involve interactions with one or more software agents.

Figure **34** is a detail flowchart for operation **1860** of figure **33** in accordance with an embodiment. Operation **1860** starts the operations of this flowchart. Arrow **1900** designates the flow of execution from starting operation **1860** to operation **1902**. Operation **1902** selects a context list. Arrow **1904** designates the flow of execution from operation **1902** to operation **1906**. Operation **1906** selects a context from the selected context list. Arrow **1908** designates the flow of execution from operation **1906** to operation **1910**. Operation **1910** selects a relationship from the relationship collection. Arrow **1912** designates the flow of execution from operation **1910** to operation **1914**.

Operation **1914** determines if the selected relationship applied to the selected context is within the relationship satisfaction range. Arrow **1916** designates the flow of execution from operation **1914** to operation **1918**, when the selected relationship applied to the selected context is not within the relationship satisfaction range. Arrow **1924** designates the flow of execution from operation **1914** to operation **1926**, when the selected relationship applied to the selected context is within the relationship satisfaction range. Operation **1926** inserts the node of the selected context into the

shared node list. Arrow **1928** designates the flow of execution from operation **1926** to operation **1922**.

Operation **1918** determines whether there are relationships as yet not selected regarding the selected context of the selected context list. Arrow **1920** designates the flow of execution from operation **1918** to operation **1922**, when there are no relationships as yet unselected regarding the selected context of the selected context list. Arrow **1942** designates the flow of execution from operation **1918** to operation **1910**, when there are no yet unselected relationships regarding the selected context of the selected context list.

Operation **1922** determines whether there are more contexts in the selected context list as yet unselected. Arrow **1932** designates the flow of execution from operation **1922** to operation **1934**, when there are no remaining unselected contexts in the selected context list. Arrow **1930** designates the flow of execution from operation **1922** to operation **1906**, when there are remaining unselected contexts in the selected context list.

Operation **1934** determines whether there are more unselected context lists. Arrow **1938** designates the flow of execution from operation **1934** to operation **1940**, when there are no more unselected context lists. Arrow **1936** designates the flow of execution from operation **1934** to operation **1902**, when there are more unselected context lists. Operation **1940** exits the operations of this flowchart.

Operation **1860** starts the operations of this flowchart. In certain embodiments, starting operation **1860** initializes the shared node list. In certain embodiments, starting operation **1860** signals other processes performing tasks, which may include but are not limited to maintenance operations upon the context lists and relationship collection, that these entities are in use, stalling such operations from being performed. In certain embodiments, starting operation **1860** allocates temporarily system resources used by the operations of this flowchart.

Operation **1940** exits the operations of this flowchart. In certain embodiments, starting operation **1940** signals other processes performing tasks, which may include but are not limited to maintenance operations upon the context lists and relationship collection, that these entities are in no longer use, allowing such operations to be

performed. In certain embodiments, starting operation **1940** releases temporarily allocated system resources used by the operations of this flowchart.

The effect of the operations of this flowchart is that if the salience of a relationship applied to a context of a context list is within the satisfaction range of the relationship, then the node of the context is inserted into the shared node list. This activity is performed across all contexts of all context lists. It is shown illustratively as a sequential process acting upon one selected relationship and one selected context within the selected context list. This is done strictly for illustrative purposes and is not meant to limit the concurrency of the execution process of the relevant operations.

10        Operation **1902** selects a context list from a plurality of context lists. After the first iteration of operation **1902** within the execution of this flowchart, the selection chooses context lists not previously selected, in certain embodiments.

Operation **1906** selects a context from the selected context list. After the first iteration of operation **1906** within the execution of this flowchart, the selection chooses contexts not previously selected, in certain embodiments.

Operation **1910** selects a relationship from the relationship collection. After the first iteration of operation **1910** within the execution of this flowchart, the selection chooses relationships not previously selected, in certain embodiments.

20        Operation **1940** further signals other potentially concurrent processes which might perform maintenance upon the context list and relationship collection, that they are no longer in use and are available for maintenance activities which might alter the results of this flowchart, in certain embodiments. Operation **1940** may further release systems resources allocated at the start of operation **1860** in certain embodiments.

25        This flowchart may have concurrent operations performed in certain embodiments, such as the application of a relationship to more than one context in parallel. Operation **1906** would select more than one context from the selected context list. Operation **1914** would apply the selected relationship to the multiplicity of selected contexts concurrently in certain further embodiments. Alternatively, the selection of contexts may act to load a cache memory, while the application of the

selected relationship may be performed concurrently in a sequential manner upon the preloaded contexts.

This flowchart may be sequentially performed in certain embodiments in essentially the order represented by this flowchart. In certain alternative  
5       embodiments, the application of a relationship may be performed first across all contexts of each context list, before a second relationship is applied across all contexts of each context list.

Figure 35 is a detail flowchart for operation 1860 of figure 33 in accordance with an alternative embodiment.

10       Operation 1860 starts by allocating systems resources in certain embodiments. Arrow 2000 designates the flow of execution from operation 1860 to operation 2002. Operation 2002 selects a context list from a plurality of context lists. Arrow 2004 designates the flow of execution from operation 2002 to operation 2006. Operation 2006 selects a context from the selected context list. Arrow 2008 designates the flow  
15       of execution from operation 2006 to operation 2010. Operation 2010 selects a relationship from the relationship collection. Arrow 2012 designates the flow of execution from operation 2010 to operation 2014.

Operation 2014 determines if the selected relationship, when applied to the selected context has salience within the satisfaction range associated with the  
20       relationship. Arrow 2016 designates the flow of execution from operation 2014 to operation 2018, when the selected relationship applied to the selected context has salience within the associated satisfaction range. Arrow 2032 designates the flow of execution from operation 2014 to operation 2028, when the selected relationship applied to the selected context has salience not within the associated satisfaction  
25       range.

Operation 2018 determines if there are more unselected relationships for the selected context of the selected context list. Arrow 2020 designates the flow of execution from operation 2018 to operation 2010, when there are more unselected relationships. Arrow 2022 designates the flow of execution from operation 2018 to  
30       operation 2024, when there are no more unselected relationships.

Operation **2024** inserts the node of the selected context into the shared node list. Arrow **2026** designates the flow of execution from operation **2024** to operation **2028**. Operation **2028** determines whether there are more unselected context lists. Operation **2028** determines whether there are more unselected relationships in the relationship collection. Arrow **2030** designates the flow of execution from operation **2028** to operation **2006**, when there are more unselected relationships. Arrow **2034** designates the flow of execution from operation **2028** to operation **2036**, when there are no more unselected relationships.

Operation **2036** determines whether there are more unselected contexts in the selected context list. Arrow **2038** designates the flow of execution from operation **2036** to operation **2002**, when there are more unselected contexts in the selected context list. Arrow **2040** designates the flow of execution from operation **2036** to operation **2042** when there are no more unselected contexts in the selected context list. Operation **2042** exits the operations of this flowchart.

The overall effect of this flowchart is to describe a process where if all relationships are satisfied by a context, the node of that context is inserted into the shared node list.

Operation **1860** further starts by initializing the shared node list in certain embodiments. In certain alternative embodiments, operation **1860** further starts configuring the shared node list to be extended. Operation **1860** further starts by signaling other potentially concurrent processes which might perform maintenance upon the context list and relationship collection, that they are in use and not available for maintenance activities which might alter the results of this flowchart, in certain embodiments.

Operation **2002** selects a context list from a plurality of context lists. After the first iteration of operation **2002** within the execution of this flowchart, the selection chooses context lists not previously selected, in certain embodiments.

Operation **2006** selects a context from the selected context list. After the first iteration of operation **2006** within the execution of this flowchart, the selection chooses contexts not previously selected, in certain embodiments.

Operation **2010** selects a relationship from the relationship collection. After the first iteration of operation **2010** within the execution of this flowchart, the selection chooses relationships not previously selected, in certain embodiments.

5        Operation **2042** further signals other potentially concurrent processes which might perform maintenance upon the context list and relationship collection, that they are no longer in use and are available for maintenance activities which might alter the results of this flowchart, in certain embodiments. Operation **2042** may further release systems resources allocated at the start of operation **1860** in certain embodiments.

10       This flowchart may be sequentially performed in certain embodiments in essentially the order represented by this flowchart. In certain alternative embodiments, the application of a relationship may be performed first across all contexts of each context list, before a second relationship is applied across all contexts of each context list.

15       This flowchart may have concurrent operations performed in certain embodiments, such as the application of a relationship to more than one context in parallel. Operation **2006** would select more than one context from the selected context list. Operation **2014** would apply the selected relationship to the multiplicity of selected contexts concurrently in certain further embodiments. Alternatively, the selection of contexts may act to load a cache memory, while the application of the  
20       selected relationship may be performed concurrently in a sequential manner upon the preloaded contexts.

Figure **36A** is a detail flowchart for operation **1408** of figures **27**, **30** and **33** in accordance with an embodiment.

25       Operation **1408** starts by allocating systems resources in certain embodiments. Arrow **2100** designates the flow of execution from operation **1408** to operation **2102**. Operation **2102** selects a first node of the shared node list. Arrow **2104** designates the flow of execution from operation **2102** to operation **2106**. Operation **2106** displays the first node. Arrow **2108** designates the flow of execution from operation **2106** to operation **2110**.

Operation **2110** determines whether to exit the operations of this flowchart. Arrow **2112** designates the flow of execution from operation **2110** to operation **2102**, when the determination is made not to exit the operations of this flowchart. Arrow **2114** designates the flow of execution from operation **2110** to operation **2116** when the determination is made to exit the operations of this flowchart. Operation **2116** exits the operations of this flowchart.

In certain embodiments, a node belonging to the shared list may be selected more than once as the iterative performance of operation **2102** progresses through time. In certain embodiments, the selection of a first node in operation **2102** is driven by software providing a script by which various nodes are displayed from the shared node list. In certain embodiments, the selection of a first node involves interaction with an external agent to the computer executing this process. In certain further embodiments, the external agent is a user. In certain other, further embodiments, the external agent is a software agent.

Figure **36B** is a detail flowchart for operation **2106** of figure **36A** in accordance with an embodiment.

Operation **2106** starts by allocating systems resources in certain embodiments. Arrow **2120** designates the flow of execution from operation **2106** to operation **2122**. Operation **2122** determines whether the first node includes content. Arrow **2124** designates the flow of execution from operation **2122** to operation **2126**, when the first node includes content. Arrow **2132** designates the flow of execution from operation **2122** to operation **2130** when the first node does not include content.

Operation **2126** displays the first node content. Arrow **2128** designates the flow of execution from operation **2126** to operation **2130**. Operation **2130** exits the operations of this flowchart.

Figure **37** is a detail flowchart for operation **2136** of figure **36B** in accordance with an embodiment. Operation **2126** starts operations of this flowchart. Arrow **2200** designates the flow of execution from starting operation **2126** to arrow **2202** and to arrow **2204**. Arrows **2202** and **2204** designate potentially concurrent activation of operations involving the audio and image content of the first node. Arrow **2200** combined with arrow **2202** designates the flow of execution from starting operation

**2126** to operation **2206**. Arrow **2200** combined with arrow **2204** designates the flow of execution from starting operation **2126** to operation **2218**.

Operation **2206** determines whether the first node includes audio content. Arrow **2208** designates the flow of execution from operation **2206** to operation **2210**,  
5 when the first node includes audio content. Arrow **2216** designates the flow of execution from operation **2206** to operation **2214** when the first node does not include audio content. Operation **2210** displays the first node audio content. Arrow **2212** designates the flow of execution from operation **2210** to operation **2214**. Operation **2214** effects an exit from the audio operations of this flowchart.

10 Operation **2218** determines whether the first node includes visual content. Arrow **2220** designates the flow of execution from operation **2218** to arrow **2222** and to arrow **2224**, when whether the first node includes visual content. Arrows **2222** and **2224** designate potentially concurrent activation of operations involving the still image content and the motion video content of the first node. Arrow **2250** designates  
15 the flow of execution from operation **2218** to operation **2242** when whether the first node includes visual content. Arrow **2220** combined with arrow **2222** designates the flow of execution from operation **2118** to operation **2226**. Arrow **2220** combined with arrow **2224** designates the flow of execution from operation **2118** to operation **2238**.

Operation **2226** determines whether the first node includes still image content.  
20 Arrow **2228** designates the flow of execution from operation **2226** to operation **2230**, when the first node includes still image content. Arrow **2234** designates the flow of execution from operation **2226** to operation **2242** via arrow **2236** when the first node does not include still image content.

Operation **2238** determines whether the first node includes motion video  
25 content. Arrow **2228** designates the flow of execution from operation **2238** to operation **2230**, when whether the first node includes motion video content. Arrow **2240** designates the flow of execution from operation **2238** to operation **2242** via arrow **2236** when whether the first node includes motion video content.

In certain embodiments, concurrent activity in operations **2210**, **2230** and **2246**  
30 may include an audio sequence, still images and motion video sequence integrated into form a single experience intended as the content of the first node. In certain

embodiments, integration of audio, still image and motion video requires synchronization between operations **2210**, **2230** and **2246**, as will be apparent to one of ordinary skill in the art. This flowchart leaves silent these issues, which are performed via standard system functions inherent in such embodiments.

5           In certain embodiments, the audio and motion video sequence may be stored in a combined audio-video stream implemented as some form of MPEG. The separation of such streams and the independent processing of the audio and video stream are not the subject of this invention and are well known to one of ordinary skill in the art.

10           In certain embodiments, the audio content may consist of more than one audio voice, which operation **2210** mixes to create the displayed audio content.

Figure **38** is a flowchart of command processing for a system in accordance with an embodiment. Starting operation **2300** performs the initial shared node list command processing.

15           Arrow **2304** designates the flow of execution and communication from starting operation **2300** to operation **2306** to process requests regarding maintaining the context list collection. Operation **2306** maintains the context list collection. Arrow **2308** designates the flow of execution from operation **2306** to operation **2310**.

20           Arrow **2314** designates the flow of execution and communication from starting operation **2300** to operation **2316** to process requests regarding maintaining the relationship collection. Operation **2316** maintains the relationship collection. Arrow **2318** designates the flow of execution from operation **2316** to operation **2310**.

25           Arrow **2320** designates the flow of execution and communication from starting operation **2300** to operation **2322** to process requests regarding shared node list generation. Operation **2322** generates the shared node list. Arrow **2324** designates the flow of execution from operation **2322** to operation **2310**.

Operation **2310** determined whether there are more shared node list commands to process. Arrow **2302** designates the flow of execution and communication from starting operation **2310** to operation **2310**, when there are more shared node list

commands to process. Arrow **2326** designates the flow of execution to operation **2312**, when there are no more shared node list commands to process. Operation **2312** exits the operations of this flowchart.

5 In certain embodiments, an object oriented software paradigm may provide the implementation framework for the implementation of the operations of this flowchart. In certain further embodiments, message passing provides the mechanism by which execution and data are transfer from one operation to another operation in this flowchart. In certain further embodiments, various operations of this flowchart may be performed concurrently. Please see the previous discussions of figures **27** to **35**  
10 regarding the use of permission mechanisms to lock the context list collections and relationship collections while shared node list generation operations are performed.

Figure **39** is a detail flowchart for operation **2306** of figure **38** in accordance with an embodiment. Starting operation **2330** performs the initial context list maintenance command processing.

15 Arrow **2328** designates the flow of execution and communication from starting operation **2330** to operation **2330** to process requests regarding maintaining a context list. Operation **2330** maintains a context list. Arrow **2332** designates the flow of execution from operation **2330** to operation **2334**.

20 Arrow **2338** designates the flow of execution and communication from starting operation **2330** to operation **2340** to process requests regarding adding a context list. Operation **2340** adds a context list. Arrow **2342** designates the flow of execution from operation **2340** to operation **2334**.

25 Arrow **2344** designates the flow of execution and communication from starting operation **2330** to operation **2346** to delete a context list. Operation **2346** deletes a context list. Arrow **2348** designates the flow of execution from operation **2346** to operation **2334**.

30 Operation **2334** determined whether there are more context list maintenance commands to process. Arrow **2350** designates the flow of execution and communication from starting operation **2334** to operation **2334**, when there are more context list maintenance commands to process. Arrow **2352** designates the flow of

execution to operation **2336**, when there are no more context list maintenance commands to process. Operation **2336** exits the operations of this flowchart.

In certain embodiments, an object oriented software paradigm may provide the implementation framework for the implementation of the operations of this flowchart.

- 5 In certain further embodiments, message passing provides the mechanism by which execution and data are transfer from one operation to another operation in this flowchart. In certain further embodiments, various operations of this flowchart may be performed concurrently.

- 10 Figure **40** is a detail flowchart for operation **2330** of figure **39** in accordance with an embodiment. Starting operation **2330** performs the initial context maintenance command processing.

- Arrow **2362** designates the flow of execution and communication from starting operation **2330** to operation **2364** to process requests regarding maintaining a context. Operation **2364** maintains the context. Arrow **2366** designates the flow of execution from operation **2364** to operation **2392**.

Arrow **2372** designates the flow of execution and communication from starting operation **2330** to operation **2374** to process requests regarding adding a context. Operation **2374** adds a context. Arrow **2376** designates the flow of execution from operation **2374** to operation **2392**.

- 20 Arrow **2382** designates the flow of execution and communication from starting operation **2330** to operation **2384** to process deleting a context. Operation **2384** deletes a context. Arrow **2386** designates the flow of execution from operation **2384** to operation **2392**.

- Operation **2392** determined whether there are more context maintenance commands to process. Arrow **2390** designates the flow of execution and communication from starting operation **2392** to operation **2392**, when there are more context maintenance commands to process. Arrow **2394** designates the flow of execution to operation **2396**, when there are no more context maintenance commands to process. Operation **2396** exits the operations of this flowchart.

In certain embodiments, an object oriented software paradigm may provide the implementation framework for the implementation of the operations of this flowchart. In certain further embodiments, message passing provides the mechanism by which execution and data are transfer from one operation to another operation in this  
5 flowchart. In certain further embodiments, various operations of this flowchart may be performed concurrently.

Figures 38, 39 and 40 taken collectively have been presented to illustrate a simple, modular approach to making and using a useful collection of operations to develop and maintain a collection of context lists and collection of relationships, as  
10 well as generate a shared node list from them. In certain embodiments, commands regarding the operations maintaining context list collections, context lists and contexts, operations maintaining relationship collections, relationships and operations generating shared node lists might be distributed from a single command processor similar to operation 2300 while removing the necessity of operations 2306 and 2330.  
15 Implementation variations of this sort will be apparent to anyone of ordinary skill in the art.

Figure 41 is a detail flowchart for operation 2322 of figure 38 in accordance with an embodiment. Starting operation 2322 in certain embodiments includes allocation of systems resources for the performance of the operation of this flowchart.  
20 Arrow 2400 designates the flow of execution from starting operation 2322 to operation 2402. Operation 2402 request generation of the shared node list from the context list collection and relationship collection. Arrow 2404 designates the flow of execution from operation 2402 to operation 2406. Operation 2406 retrieves the shared node list generated from the context list collection and relationship collection.  
25 Arrow 2408 designates the flow of execution from operation 2406 to operation 2410. Operation 2410 exits the operations of this flowchart.

Figure 42 is a detail flowchart for operation 2322 of figure 38 in accordance with an embodiment. Starting operation 2322 in certain embodiments includes allocation of systems resources for the performance of the operation of this flowchart.  
30 Arrow 2450 designates the flow of execution from starting operation 2322 to operation 2452. Operation 2452 receives a request for generation of the shared node list from the context list collection and relationship collection. Arrow 2454 designates

the flow of execution from operation **2452** to operation **2456**. Operation **2456** processes a request for generation of the shared node list from the context list collection and relationship collection. Arrow **2458** designates the flow of execution from operation **2456** to operation **2460**. Operation **2460** transmits the generated  
5 shared node list. Arrow **2462** designates the flow of execution from operation **2460** to operation **2464**. Operation **2464** exits the operations of this flowchart.

Figure **43** is a detail flowchart for operation **2456** of figure **42** in accordance with an embodiment. Starting operation **2456** in certain embodiments includes allocation of systems resources for the performance of the operation of this flowchart.  
10 Arrow **2500** designates the flow of execution from starting operation **2456** to operation **2502**. Operation **2502** evaluates the relationship collection of the received request.

Arrow **2504** designates the flow of execution from operation **2502** to operation **1404**, when the relationship collection is found not to contain relationships with  
15 salience ranges or satisfaction choices. Operation **1404** generates of the shared node list from the context list collection and relationship collection, where the shared node list includes nodes from contexts satisfying at least one relationship. Arrow **2510**, combined with arrow **2516** designates the flow of execution from operation **1404** to operation **2518**.

20 Arrow **2506** designates the flow of execution from starting operation **2456** to operation **1608**, when the relationship collection is found not to contain relationships with salience ranges, but possessing satisfaction choices. Operation **1608** generates of the shared node list from the context list collection and relationship collection, where the shared node list includes nodes from contexts satisfying relationships with regards  
25 to associated satisfaction choices. Arrow **2512**, combined with arrow **2516** designates the flow of execution from operation **1608** to operation **2518**.

Arrow **2508** designates the flow of execution from starting operation **2456** to operation **1860**, when the relationship collection is found to contain relationships with salience ranges. Operation **1860** generates of the shared node list from the context list  
30 collection and relationship collection, where the shared node list includes nodes from contexts satisfying relationship with salience found in an associated satisfaction

range. Arrow **2514**, combined with arrow **2516** designates the flow of execution from operation **1860** to operation **2518**. Operation **2518** exits the operations of this flowchart.

Figure **44** is a flowchart of hypergraph display and traversal in accordance with an embodiment. Starting operation **2600** allocates systems resources in certain embodiments. Arrow **2602** designates the flow of execution from starting operation **2600** to operation **2604**. Operation **2604** selects a first context list from the collection of context lists. Arrow **2618** designates the flow of execution from starting operation **2600** to operation **2620**. Operation **2620** displays the collection of context lists.

Arrow **2606** designates the flow of execution from starting operation **2604** to operation **2608**. Operation **2608** selects a first context from the first context list. Arrow **2622** designates the flow of execution from starting operation **2604** to operation **2624**. Operation **2620** displays the first context list.

Arrow **2610** designates the flow of execution from starting operation **2608** to operation **2612**. Operation **2612** selects a first context from the first context list. Arrow **2626** designates the flow of execution from starting operation **2608** to operation **2628**. Operation **2628** displays the first context.

Arrow **2614** designates the flow of execution from starting operation **2612** to operation **2630**. Operation **2630** determines whether to select another context from the first context list. Arrow **2632** designates the flow of execution from starting operation **2630** to operation **2604**, when another context from the first context list is to be selected. Arrow **2634** designates the flow of execution from starting operation **2630** to operation **2636**, when another context is not to be selected from the first context list.

Operation **2636** determines whether to select another context list from the collection of context lists. Arrow **2638** designates the flow of execution from starting operation **2636** to operation **2604**, when another context list from the context list collection is to be selected. Arrow **2640** designates the flow of execution from starting operation **2636** to operation **2642**, when another context list is not to be selected from the context list collection. Operation **2642** exits the operation of this flowchart.

In certain preferred embodiments, operation **2620** and arrow **2618** are not implemented. In certain preferred embodiments, operation **2624** and arrow **2622** are not implemented. In certain preferred embodiments, operation **2628** and arrow **2626** are not implemented.

5           Figure **45A** is a detail flowchart for operation **2612** of figure **44** in accordance with an embodiment. Starting operation **2612** in certain embodiments includes allocation of systems resources for the performance of the operation of this flowchart. Arrow **2650** designates the flow of execution from starting operation **2612** to operation **2652**. Operation **2652** requests the node of the first context. Arrow **2654**  
10           designates the flow of execution from operation **2652** to operation **2656**. Operation **2656** receives the node of the first context. Arrow **2658** designates the flow of execution from operation **2656** to operation **2660**. Operation **2660** exits the operations of this flowchart.

          Figure **45B** is a detail flowchart for operation **2612** of figure **44** in accordance  
15           with an embodiment. Starting operation **2612** in certain embodiments includes allocation of systems resources for the performance of the operation of this flowchart. Arrow **2670** designates the flow of execution from starting operation **2322** to operation **2672**. Operation **2672** receives a request for the node of the first context. Arrow **2674** designates the flow of execution from operation **2672** to operation **2676**.  
20           Operation **2676** retrieves the node of the first context. Arrow **2678** designates the flow of execution from operation **2676** to operation **2480**. Operation **2480** transmits the node of the first context. Arrow **2482** designates the flow of execution from operation **2480** to operation **2484**. Operation **2484** exits the operations of this flowchart.
